Acknowledgements

I would like to express my sincere gratitude to my supervisor Prof. In-Ho Jung, who has been giving me all the decisive suggestions and led me to accomplish this research. Without his support, it is undoubtedly that I cannot achieve the success. I would like to thank my friend Guoqiang Lan and his supervisor Prof Jun Song for donating their precious time to support my research.

It is also my pleasure to get to know Dr. Pierre Hudon, who has been supporting our research group for a long time. I would like to thank Pierre to remember everyone's birthday, organize summer getaway vacations and Christmas parties. Because of Pierre, there is always happiness and love in our research group.

My deep thanks also goes to all my friends during my graduate study. I enjoyed the time with all my friends: Xintong Du, Tiantian Ying, Kota Matsuo and Zhimin You. I will not forget the time that we spent together to prepare exams in Prof. Pelton's course.

Last but not least, my father Yuanchao Zhang and grandma Guang Li have been believing in me since the very beginning of my graduate study. I may not grow into the person I am today without their encouragement. They make me confident and determined to chase my goals. I would like to dedicate this thesis to all the people I mentioned here and share my happiness with them.

Yumin Zhang, July – 2016, Montreal

Abstract

In order to develop the thermodynamic database containing rare earth sesquioxides (RE_2O_3), accurate thermodynamic descriptions of all stable and metastable RE_2O_3 phases are required. Rare earth sesquioxides have numerous polymorphs, which are (from low to high temperature) the cubic phase (labelled C), the monoclinic phase (B), the hexagonal phase (A), the high temperature hexagonal phase (H), and the high temperature cubic phase (X). However, the thermodynamic property data available for these different polymorphous are insufficient especially for the phase stable at high temperature region and also for metastable forms.

In this study, all ΔH_{298}° , S_{298}° , C_P (or heat content) and phase transition temperature (T_{tr}) data available in the literature were collected and critically evaluated for each rare earth sesquioxide based on the experimental procedures and techniques employed. Relationships between ΔH_{298}° , S_{298}° , and T_{tr} against the ionic radii of the entire rare earth sesquioxide series were then established and missing thermodynamic information was predicted. In general, the enthalpy (ΔH_{tr}°) and entropy (ΔS_{tr}°) changes of the C – B, B – A, A – H, and H – X transitions are either scarce or unavailable. For the C – B and B – A transitions, experimental enthalpy data and entropies extracted using the Clausius – Clapeyron relation were collected from the literature and employed together with results obtained from Density Functional Theory (DFT) calculations to estimate the ΔH_{tr}° and ΔS_{tr}° . Based on the observations from the RE_2O_3 liquidus in $\text{RE}_2\text{O}_3 - \text{Al}_2\text{O}_3$ binary phase diagrams, a small ΔS_{tr}° value for A – H and H – X transitions was estimated by applying so – called “limiting slope rule” to ensure smooth liquidus slope change between A and H, as well as H and X phases. Regarding the properties of fusion, the similar “limiting slope rule” was employed that a couple of phase diagram data points were taken near the pure RE_2O_3 melting points for ΔH_m and ΔS_m estimations. In these ways, the accurate and consistent Gibbs energies of all stable and metastable RE_2O_3 phases ($\text{RE} = \text{La, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb and Lu}$) are prepared. These Gibbs energy data will be ready readily used for the development of a comprehensive thermodynamic database containing rare earth oxides.

Abstract

Afin de développer la base de données thermodynamiques contenant des sesquioxydes de terre rare (RE_2O_3), des descriptions thermodynamique précises pour toutes les phases de RE_2O_3 stable et métastable sont requises. Les sesquioxydes de terres rares ont de nombreuses polymorphes, soit (en ordre de faible à haute température) la phase cubique (appelée C), la phase monoclinique (B), la phase hexagonale (A), la phase hexagonale haute température (H), et la phase cubique haute température (X). Toutefois, les données disponibles concernant les propriétés thermodynamiques pour ces différentes polymorphes sont relativement insuffisantes en particulier pour la région haute température et également pour la forme métastable.

Dans cette étude, les données pour ΔH_{298}° , S_{298}° , C_p (ou la capacité thermique) et pour les températures de transition de phase (T_{tr}) disponibles dans la littérature ont été recueillies et évaluées de manière critique pour chaque sesquioxyde de terre rare sur la base des procédures expérimentales et les techniques ci-employées. Les relations entre ΔH_{298}° , S_{298}° , et T_{tr} par rapport aux rayons ioniques pour la série entière des sesquioxydes de terre rare ont ensuite été établies et l'information thermodynamique absente a été prédite. En général, les changements en enthalpie (ΔH_{tr}°) et en entropie (ΔS_{tr}°) pour les transitions C – B, B – A, A – H, et H – X sont rares ou inexistants. Pour les transitions C – B et B – A, des données expérimentales pour entropies et enthalpies extraites en utilisant la relation de Clausius-Clapeyron ont été recueillies de la littérature et employées ensemble avec les résultats obtenus à partir de calculs utilisant la théorie de la fonctionnelle de la densité (DFT, de l'anglais *density functional theory*) pour estimer les valeurs de ΔH_{tr} et ΔS_{tr} . Se basant sur les observations provenant du liquidus de RE_2O_3 dans les diagrammes de phases binaires RE_2O_3 - Al_2O_3 , une petite valeur de ΔS_{tr}° pour les transitions A – H et H – X a été estimée en appliquant la "règle de pente" pour assurer un changement en douceur de la pente du liquidus entre les phases A et H, ainsi qu'entre les phases H et X. En ce qui concerne les propriétés de fusion, la "règle de pente" a aussi été employée tel qu'un couple de points de données du diagramme de phase ont été prises près des points de fusion de RE_2O_3 purs pour les estimations de ΔS_{tr} . De cette façon, les énergies de Gibbs pour toutes les phases de RE_2O_3 stables et métastables (RE = La, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb et Lu) sont préparées pour l'extension vers des systèmes binaires et à composants multiples.

1. Introduction

RE_2O_3 (rare earth sesquioxides) include the whole series of lanthanide sesquioxides from La_2O_3 to Lu_2O_3 and two rare earth like sesquioxides: Y_2O_3 and Sc_2O_3 . The “sesquioxide” simply indicates oxide which has two moles of cations and three moles of oxygen anions in each mole of oxide. RE_2O_3 have a wide range of applications because of their unique physical and chemical properties. One of the most important applications is to use RE_2O_3 as ZrO_2 stabilizers. ZrO_2 is commonly used as heat resistant material on gas engine turbines to protect Ni – based superalloy. The most widely used RE_2O_3 stabilized ZrO_2 system is YSZ (yttrium stabilized zirconia), which is originally developed by NASA in the mid 1970s. Nowadays, a lot of efforts have been poured into researching of more advanced alternative RE_2O_3 – stabilized – ZrO_2 aiming lower thermal conductivity and better durability [1]. Several candidates are Gd_2O_3 , Sm_2O_3 and Nd_2O_3 sesquioxides [1]. Rare earth metals and oxides are highly desired in battery, advanced ceramics and military industries. Though rare earth oxides have a wide range of strategic and critical applications, the thermodynamic properties and phase diagrams are still not well determined. For example, neither the Gibbs energies for all stable nor metastable RE_2O_3 are accurately established.

Several years ago, a comprehensive review of thermodynamic properties of RE_2O_3 was performed by Zinkevich [2], who studied standard enthalpy, entropy, C_p and phase stabilities. Basing on his own study, the Gibbs energy data of RE_2O_3 were validated by applying on $\text{RE}'_2\text{O}_3$ – $\text{RE}''_2\text{O}_3$ phase diagrams. Some of the thermodynamic properties of metastable phases were then deduced from calculated phase diagrams. Some disagreements between assessed results by Zinkevich and experimental data regarding transition temperatures of RE_2O_3 were found. Some of the thermodynamic transition enthalpy and temperature properties of metastable RE_2O_3 were not clearly reported in the work of Zinkevich. Furthermore, the experimental transition enthalpy of $\text{A} \rightarrow \text{H}$ transition adopted by Zinkevich was questionably large, which can introduce significantly unreliable estimation of Gibbs energy of A and H phases. Therefore, it is necessary to review all the thermodynamic properties of RE_2O_3 again to produce a more unequivocal and consistent thermodynamic data for entire RE_2O_3 database.

In this study, the completed literature is divided into four parts: (1) phase transition temperatures, (2) standard enthalpies of formation, standard entropies and heat capacity functions, (3) phase transition enthalpies and entropies, and (4) binary $\text{RE}'_2\text{O}_3 - \text{RE}''_2\text{O}_3$ phase diagrams. In the first part, the thermal stability and phase transition of each RE_2O_3 were discussed. The best set of transition temperature values for stable and metastable RE_2O_3 phases (five solid polymorphs and one liquid phase) were determined. In the second part, numerous experimental data ΔH_{298}° and S_{298}° were critically assessed and unavailable data were estimated. In the third part, due to limited quantity of experimental data, several methodologies were employed to estimate enthalpy and entropy of transitions. The T_{tr} estimated in conjunction with the studies of transition energies were inserted back to the corresponding T_{tr} sections. In the last part, the constructed thermodynamic database of RE_2O_3 from the previous three parts was employed to the binary $\text{RE}'_2\text{O}_3 - \text{RE}''_2\text{O}_3$ phase diagrams for validation purposes of the accuracy of new RE_2O_3 database model.

2. Temperatures of Polymorphs Phase Transitions

Rare earth sesquioxides have different stable crystal structures at room temperature and pressure. The Lanthanide oxides from La_2O_3 to Nd_2O_3 , generally called as the light RE_2O_3 , are stable as hexagonal structure – A phase; Sm_2O_3 to Gd_2O_3 , named as the middle RE_2O_3 , are stable in either monoclinic – B or cubic – C phases; Tb_2O_3 to Lu_2O_3 , named as the heavy RE_2O_3 , are stable in only cubic – C phase. The Pm_2O_3 , which positions between the light and middle RE_2O_3 , is stable in C phase. Three stable phases C, B and A of RE_2O_3 exist at room temperature. When temperature is raised above 2400K, three room temperature phases transfer to high temperature hexagonal – H and high temperature cubic – X. According to Foex and Traverse [3] in 1960s, these two high temperature phases are just below the melting points but not quenchable to room temperature.

Aldebert and Traverse [4] in 1970s studied the crystal structures of H and X phases using neutron diffraction experiments. In their study, the positions of oxygen atoms in H phase were reasonably determined, but the position of oxygen atoms in X phase are still ambiguous. Therefore, it is difficult to even preform DFT based chemical and physical calculations due to no reliable

crystal structure information of such high temperature phases. Therefore, further study on crystal structures of H and X phases are very necessary.

Ideally, the polymorph transitions of RE_2O_3 occur in the sequence of $C \rightarrow B \rightarrow A \rightarrow H \rightarrow X \rightarrow L$ from room temperature to high temperatures. However, some of the transitions become inviable at room pressure especially when ionic radii [5] become smaller from La_2O_3 to Lu_2O_3 . According to experimental data, phase transition of the light RE_2O_3 follow the sequence of $A \rightarrow H \rightarrow X \rightarrow L$, while the other sesquioxides all transform from C phase. The middle RE_2O_3 and Pm_2O_3 obey the ideal transition sequence of $C \rightarrow B \rightarrow A \rightarrow H \rightarrow X \rightarrow L$; and Tb_2O_3 to Dy_2O_3 generally obey the ideal transition without A phase, Ho_2O_3 and Y_2O_3 without A or X phases; Er_2O_3 to Yb_2O_3 transform in the order of $C \rightarrow H \rightarrow L$; Lu_2O_3 and Sc_2O_3 maintain as C structure up to their meltings.

The importance of proper understanding of polymorphic transition urged many investigations starting from Goldschmidt et al., [6] in 1925. In 1961, Warshaw and Roy [7] studied the $C \rightarrow B$ transition temperatures of selective RE_2O_3 ($RE = La - Nd, Sm - Gd, Tb, \text{ and } Dy$) using classical quenching technique with XRD phase analysis. The first comprehensive study of almost entire lanthanide RE_2O_3 involving all the phase transitions until melting was carried out by Foex and Traverse [3] using *in situ* thermal and X – ray analysis. In their study, the measured T_{tr} and T_{fus} were plotted in terms of atomic numbers of the Lanthanide cations to produce a phase transition diagram with provisional phase boundaries. The $T_{tr,C \rightarrow B}$ of Pm_2O_3 was an approximation by Foex and Traverse from their study and result by Weigel and Scherer [8], who studied C, B and A crystal structures of Pm_2O_3 . A few years later, Tresvyatkii et al. [9] measured the T_{tr} of some RE_2O_3 ($RE = La - Nd, Sm, Gd, Tb - Er, Yb \text{ and } Y$) using DTA and XRD methods. The reversibility of the phase transitions with increasing and decreasing temperature was demonstrated in their work. Coutures and Foex [10] carried out selective binary phase diagram studies of $La_2O_3 - RE'_2O_3$ systems using TA and XRD methods. They produced the phase diagrams at high temperatures mainly involving H, X and liquid phases. T_{tr} of pure RE_2O_3 can be extracted from these binary phase diagrams as illustrated in Figure 1. Since it was a collaboration between Coutures and Foex [10], excellent agreement with the original work by Foex and Traverse [3] was observed. The most recent comprehensive study of T_{tr} of RE_2O_3 , excluding Pm_2O_3 and Eu_2O_3 , was performed by Shevthenko and Lopato [11] in 1985 using DTA method in controlled gaseous

environment up to 2873K and TA method in air using solar radiation heating up to 3273K. All the results from these four most comprehensive investigations and some fragmental studies are discussed below, and compared for each phase transition in the following sections 2.1 to 2.6. The best and most reliable set of data were selected in this work and hypothetical transition temperatures for metastable phases were predicted reasonably. Some necessary comparisons between this work and the previous assessment from Zinkevich [2] were also made.

2.1 Temperatures of C→B Phase Transition

The existence of the C→B transition from Pm_2O_3 to Ho_2O_3 is well observed by various authors [3, 9-11]. This transition is yet debatable for Er_2O_3 and Yb_2O_3 : for example, in the study by Tresvyatkii et al. [9], mixed or combined phase transitions (1) C→B, B→A→H for Er_2O_3 and (2) C→B→A→H transitions for Yb_2O_3 were observed at single temperatures 2593K and 2653K respectively. Details on the experimental data and assessed values are listed in Table 4 and Figure 2.

Chikalla et al. [12] obtained B polymorph from C – Pm_2O_3 by heating promethium oxalate at 923 – 1023K for 1 week. This is the only experimental study for Pm_2O_3 available in literature. Zinkevich [2] proposed 457K as the transition temperature, which were estimated from the T_{tr} from Sm_2O_3 to Gd_2O_3 . It should be noted that the C→B transition temperatures proposed by Zinkevich from Sm_2O_3 to Gd_2O_3 were also lower than the experimental values [7, 13-15]. In this study, results from Chikalla et al. on Pm_2O_3 is accepted because of strong experimental evidences. The $T_{\text{tr,C} \rightarrow \text{B}}$ of Pm_2O_3 in this study is 973K, which is the middle value of the experimental findings (923 – 1023K) of Chikalla et al.

The transitions of Sm_2O_3 , Eu_2O_3 and Gd_2O_3 were measured using heat treatment and XRD analysis [7, 13, 15]. Roth and Schneider [13] reported the annealing of C form of Sm_2O_3 at several temperatures up to 1173K for 1 – 2 weeks did not produce B form, but heating at 1273K for a few hours readily formed B phase, which indicated the transition temperature is between 1173K and 1273K. Later Warshaw and Roy [7] found the formation of the B form Sm_2O_3 at 1153K after 20 hours annealing, which is more or less consistent with Roth and Schneider. In the present study,

the result from Warshaw and Roy is accepted because of excellent alignment with $T_{tr,C \rightarrow B}$ of neighboring sesquioxides Eu_2O_3 , Gd_2O_3 and Pm_2O_3 in Figure 2.

For Eu_2O_3 , Curtis and Tharp [15] reported $C \rightarrow B$ transition at about 1323K, but it was not reversibly reproducible. They suggested that C form was either metastable or had extremely slow transition mechanism during the reversion process. Roth and Schneider [13] later performed the same experiment of Curtis but did not find transformation even after 100 hours annealing at 1323K. Roth and Schneider suggested 1348K as transition temperature. The result of Roth and Schneider was later well supported by Warshaw and Roy [7], who found a small amount of B form when heating C sample at 1378K for 30 hours. In the literature, the transition temperature of Eu_2O_3 by Roth and Schneider is widely accepted and employed by both Fitzgibbon et al. [16] and Lyutsareva et al. [17] for the calculation of ΔH_{tr}° . In the present study, 1348K is also accepted as the $C \rightarrow B$ transition temperature of Eu_2O_3 .

Roth and Schneider [13] observed the $C \rightarrow B$ transition of Gd_2O_3 at 1523K after several days of annealing. Warshaw and Roy [7] reported the $C \rightarrow B$ transition at 1508K after 20 hours annealing. A slightly higher transition temperature 1561K was reported by Kolitsch [18]. Considering the consistency of the results of Kolitsch with the whole middle RE_2O_3 , 1561K is accepted as the $C \rightarrow B$ transition temperature of Gd_2O_3 .

Zinkevich [2] estimated the $C \rightarrow B$ transition temperatures of Sm_2O_3 , Eu_2O_3 and Gd_2O_3 from the optimized binary phase diagrams of $Y_2O_3 - Sm_2O_3$, $Y_2O_3 - Eu_2O_3$ and $Y_2O_3 - Gd_2O_3$ as shown in Figure 3. But the temperatures are much lower than the real experimental data explained above.

Warshaw and Roy [7] reported $C \rightarrow B$ transition for Tb_2O_3 to be around 2113K. However, Warshaw's experiments might suffer from slow kinetics of phase transition, which caused unusual high temperature. Results discovered by Foex and Traverse [3] suggested $T_{tr,C \rightarrow B}$ located between 1679 and 1829K. 1823K can be extracted from the $T_{tr} -$ Ionic radii phase diagram by Foex and Traverse. Zinkevich [2] obtained 1823K from the analysis of the relationship between temperature and pressure of phase transition from the study of Hoekstra [19] and recommended 1823K for $C \rightarrow B$ transition. In the present study, 1823K is accepted for $C \rightarrow B$ transition temperature for Tb_2O_3 .

DTA and TA data for C→B transition of Dy₂O₃ were reported by several authors [3, 9-11]. Tresvyatkii et al. [9], Foex and Traverse [3] reported exactly same T_{tr}=2223K, and a slightly higher value 2353K was reported by Shevthenko and Lopato [11]. The transition temperature of 2140K from the binary La₂O₃ – Dy₂O₃ phase diagram of Coutures and Foex [10] could be roughly extrapolated, but this value could be unreliable due to lack of data in Dy₂O₃ rich region. On the present study, the average temperature 2238K of Foex and Traverse, Tresvyatkii et al., Shevthenko and Lapoto is accepted.

Ho₂O₃ is the last RE₂O₃ which has stable C→B transition at 1 atm. Transition temperatures measured by [3, 9-11] using TA and DTA methods are in good agreement and the average 2460K is taken in this study.

Regarding the phase transitions of Er₂O₃, many authors [3, 10, 11] agreed that the C→B transition was no longer existed. However, Tresvyatkii et al. [9] reported transitions of C→B and B→A→H occurred concurrently at 2593K. In this study, C→H transition is accepted for Er₂O₃ instead of the mixed transition suggested by Tresvyatkii et al. To ensure the slight instability of B phase against H phase, T_{tr,C→B} for Er₂O₃ was intentionally raised slightly higher to 2600K rather than 2593K for C→H transition temperature. Details of C→H transition will be found in 2.6.1.

Metastable transition temperature of C→B of RE₂O₃ (RE = Tm – Lu, Y, Sc) should be estimated in order to develop the full thermodynamic database. *Figure 2* shows the variation of C→B transition temperature with ionic radii of RE₂O₃ cations. As can be seen in *Figure 2*, the experimental C→B transition temperatures of Dy₂O₃ to Sm₂O₃ is linearly shaped with ionic radii of RE³⁺. This linear trend is extrapolated and extended to heavy RE₂O₃ (Tm₂O₃ – Lu₂O₃) and Sc₂O₃. Y₂O₃ was specially treated because the value calculated from the linear relationship was lower than assessed T_{tr,C→H} (as seen in Table 9). During estimation, it is necessary to ensure the metastable T_{tr,C→B} is higher than stable transitions T_{tr,C→H} and T_{tr,C→L}. Otherwise, for example, the linearly extrapolated T_{tr,C→B} for Y₂O₃ could produce C→B→H transition instead of C→H transition. The average value 2756K calculated from T_{tr,C→B} of Er₂O₃ and Tm₂O₃ was accepted for T_{tr,C→B} of Y₂O₃ in this study.

The metastable $T_{tr,C \rightarrow B}$ of light RE_2O_3 ($RE = La - Nd$, stable phase transition starts from A phase) were calculated using optimized ΔH_{tr}° and ΔS_{tr}° of C to B transition. The details of the optimization process of ΔH_{tr}° and ΔS_{tr}° will be discussed in section 6.2.1. It should be noted that the optimized metastable $T_{tr,C \rightarrow B}$ of light RE_2O_3 show the continuous linear relationship between T_{tr} and ionic radii, as can be seen in Figure 2.

2.2 Temperatures of B→A Phase Transition

The B→A transition was confirmed to exist from Pm_2O_3 to Eu_2O_3 by many researchers [3, 8-11]. However, inconsistency in the literature was observed starting from Gd_2O_3 where mixed transitions occurred [9, 11]. The details of experimental, estimated and assessed values can be found in Table 5 and Figure 3.

The A form of Pm_2O_3 was obtained by Weigel and Scherer [8] after heating $Pm(OH)_3$ above 1873K in air or argon environment for several hours. A similar value $T_{tr,B \rightarrow A}$ 2013K for Pm_2O_3 was also reported by Chikalla et al. [12] using DTA technique. Differently, Zinkevich [2] recommended 936K, a much lower temperature than both experimental data [8, 12]. The result of Chikalla et al. showed consistent with the general B→A transition trend of adjacent sesquioxides, therefore is accepted in this study.

The experimental $T_{tr,B \rightarrow A}$ of Sm_2O_3 were reported by many researchers [3, 9-11] using TA and DTA techniques. Excellent agreements were found in three studies [3, 9, 11] except the work by Coutures and Foex [10]. In fact, the result of Coutures was extracted presumably from the binary $La_2O_3 - Sm_2O_3$ phase diagram. Therefore, the average value 2170K calculated using three studies [3, 9, 11] is accepted in this study.

The only experimental result 2323K for Eu_2O_3 is reported by Foex and Traverse [3]. This value is consistent with T_{tr} of adjacent sesquioxides as can be seen in Figure 3, therefore this temperature is accepted in this work.

The B→A transition of Gd₂O₃ was investigated by numerous researchers [3, 9-11, 20] using TA, DTA and electric conductivity methods. The two results by Foex and Traverse [3], and Coutures and Foex [10] using TA technique showed fair agreements, but lower than the results by Tresvyatkii et al. [9], Shevthenko and Lopato [11] from DTA method. The two DTA results were exactly the same in value of 2443K and in good agreement with Barkhatov et al. [20] using ECM (electric conductivity measurements) method. It should be noted that Tresvyatkii et al. discovered B→A and A→H transitions occurred in a temperature range 2443 – 2473K, and Shevthenko and Lopato determined two possible transitions B→A and B→H coexisted at a single temperature 2443K. These results indicate that the stability range of A phase is probably too small to detect. According to the phase diagram of La₂O₃ – Gd₂O₃ system by Coutures and Foex who determined B→A transition in the binary system from 70 at.% Gd₂O₃ to pure Gd₂O₃, T_{tr,B→A} of pure Gd₂O₃ is 2383K. In this study, 2383K from Coutures and Foex is taken for B→A transition of Gd₂O₃.

For Tb₂O₃, Dy₂O₃ and Ho₂O₃, B→H transition was observed by Foex and Traverse [3], A phase was not found. This is also supported by the study of Coutures and Foex [10], where the inexistence of A phase was confirmed according to their La₂O₃ – Dy₂O₃ and La₂O₃ – Ho₂O₃ phase diagrams.

On the other hand, Tresvyatkii et al., [9], Shevthenko and Lopato [11] reported the possible existence of A phase in Tb₂O₃, Dy₂O₃ and Ho₂O₃ using DTA. For Tb₂O₃, inseparable transition B→A and A→H were found by Tresvyatkii et al. at 2448K. Shevthenko and Lopato discovered B→A at 2433K, A→H and B→H simultaneously at 2448K. The similar phase transitions were also observed for Dy₂O₃ in the studies of Shevthenko and Lopato, and Tresvyatkii et al., where both works reported the same T_{tr}=2463K for B→A and A→H transitions. For Ho₂O₃, a mixture of C→B, B→A and A→H phase transitions were discovered by Tresvyatkii et al. in temperature range 2463 – 2563K. The complex phase transitions reported by Tresvyatkii et al., Shevthenko and Lopato are probably due to slow kinetics of phase transition. In this study, A phase is considered as metastable in Tb₂O₃, Dy₂O₃ and Ho₂O₃. For Tb₂O₃ – Lu₂O₃ and Sc₂O₃, temperatures of metastable B→A transition were calculated by extrapolating from the linear dependence of T_{tr,B→A} with respect to ionic radii between Gd₂O₃ at (0.938Å, 238K) and an assumed coordination (0.84Å, 2800K). In this way, the instability of metastable B→A transition and stability of B→H of these RE₂O₃ are

secured. For $\text{La}_2\text{O}_3 - \text{Nd}_2\text{O}_3$, the $\text{B} \rightarrow \text{A}$ transition is not observed because A form is stable down to room temperature. For the sake of simplicity, the hypothetical transition temperatures of $\text{B} \rightarrow \text{A}$ for $\text{La}_2\text{O}_3 - \text{Nd}_2\text{O}_3$ were estimated from the DFT results of ΔH_{tr}° of $\text{B} \rightarrow \text{A}$ by Wu et al. [119] with the assumed ΔS_{tr}° at $0.05 \text{ J/mol} \cdot \text{K}$ using Equation 5. That is $T_{tr, \text{B} \rightarrow \text{A}} = (\Delta H_{tr} / \Delta S_{tr})$.

2.3 Temperatures of $\text{A} \rightarrow \text{H}$ Phase Transition

The $\text{A} \rightarrow \text{H}$ transition was generally well-studied from La_2O_3 to Nd_2O_3 . Some confusions were reported in the works of Tresvyatkii et al. [9], Shevthenko and Lopato [11] for $\text{Gd}_2\text{O}_3 - \text{Ho}_2\text{O}_3$. All the experimental data, estimated and assessed values are listed in Table 6 and plotted in Figure 4.

“A” phase is the stable phase for $\text{La}_2\text{O}_3 - \text{Nd}_2\text{O}_3$ at room temperature. The $\text{A} \rightarrow \text{H}$ transition, was well investigated by many researchers [3, 9-11] using TA and DTA methods. Most of the data are in excellent agreement. Therefore, the averages obtained from experimental measurements for $\text{La}_2\text{O}_3 - \text{Nd}_2\text{O}_3$ were accepted in this study. For Pm_2O_3 and Eu_2O_3 , the only experimental data were reported by Chikalla et al. [12], Foex and Traverse [3] respectively, and they were accepted in this work.

Several experimental data for Sm_2O_3 were reported [3, 9-11] using TA and DTA methods. Some variations were observed. The results of Coutures and Foex [10] was accepted in this study because their results were based on $\text{La}_2\text{O}_3 - \text{Sm}_2\text{O}_3$ phase diagram.

For Gd_2O_3 , mixed transitions of $\text{B} \rightarrow \text{A}$ and $\text{A} \rightarrow \text{H}$ were reported at values 2458K and 2473K by Tresvyatkii et al. [9], Shevthenko and Lopato [11], respectively (as seen in Table 6). Other investigations by Foex and Traverse [3], Coutures and Foex [10], Barkhatov et al. [20] agreed on discrete $\text{B} \rightarrow \text{A}$ and $\text{A} \rightarrow \text{H}$ transitions even though the temperature differences between the two transitions were as small as 22 – 45K. Because of substantial evidences found [3, 10, 20], the two results of mixed transitions [9] [11] were regarded as T_{tr} of $\text{A} \rightarrow \text{H}$ transition. In this study, the average value 2447K of all available is accepted because variations of values were small.

For the heavy RE_2O_3 , starting from Tb_2O_3 , unstable $\text{A} \rightarrow \text{H}$ transition is observed. Complex transitions, involving metastable A were reported for Tb_2O_3 , Dy_2O_3 and Ho_2O_3 by Tresvyatkii et al. [9], Shevthenko and Lopato [11] who found “ $\text{B} \rightarrow \text{A} \rightarrow \text{H}$ ” and “ $\text{A} \rightarrow \text{H} \rightarrow \text{B}$ ” transitions respectively. Stable $\text{B} \rightarrow \text{H}$ transition occurs for $\text{Tb}_2\text{O}_3 - \text{Ho}_2\text{O}_3$, and stable $\text{C} \rightarrow \text{H}$ transition occurs for Y_2O_3 , $\text{Er}_2\text{O}_3 - \text{Yb}_2\text{O}_3$. The metastable $T_{\text{tr}, \text{A} \rightarrow \text{H}}$ for these heavy RE_2O_3 , Y_2O_3 and Sc_2O_3 were estimated based on experimental temperatures of combined transitions $\text{B} \rightarrow \text{H}$, $\text{C} \rightarrow \text{H}$, $\text{C} \rightarrow \text{L}$ and their corresponding transition $\Delta H_{\text{tr}}^\circ$ and $\Delta S_{\text{tr}}^\circ$. Generally, the longer the combined transition, the more assumptions were involved. For example, the Lu_2O_3 and Sc_2O_3 , which have $\text{C} \rightarrow \text{L}$ transition, are the most difficult cases because the most estimations were involved: $T_{\text{tr}, \text{H} \rightarrow \text{X}}$ and $T_{\text{tr}, \text{X} \rightarrow \text{L}}$ determined from ionic dependent temperature trend, and the calculated $\Delta H_{\text{tr}}^\circ$ and $\Delta S_{\text{tr}}^\circ$ of discrete phase transformations among C, B, A, X and L. The details will be introduced in section 6.2.3 on $\Delta H_{\text{tr}}^\circ$ and $\Delta S_{\text{tr}}^\circ$ of $\text{A} \rightarrow \text{H}$ transition. $T_{\text{tr}, \text{A} \rightarrow \text{H}}$ calculated from combined transitions for Y_2O_3 , Sc_2O_3 and $\text{Tb}_2\text{O}_3 - \text{Lu}_2\text{O}_3$ showed large fluctuations, however, the magnitudes of these estimated values are less critical as long as properties of the stable combined transitions are closely aligned to experimental results (eq. $\Delta H_{\text{tr}, \text{C} \rightarrow \text{H}}^\circ$ and $T_{\text{tr}, \text{C} \rightarrow \text{H}}$). The accepted $T_{\text{tr}, \text{A} \rightarrow \text{H}}$ of $\text{La}_2\text{O}_3 - \text{Gd}_2\text{O}_3$ in this study showed larger fluctuation than the results from Zinkevich [2]. This smooth linear temperature – ionic radii relationship might be a result of manual adjustment.

2.4 Temperatures of $\text{H} \rightarrow \text{X}$ Phase Transition

Experimental data for the $\text{H} \rightarrow \text{X}$ transition of $\text{La}_2\text{O}_3 - \text{Dy}_2\text{O}_3$ were investigated [3, 9-12] using TA and DTA techniques. RE_2O_3 after Dy_2O_3 melt directly from H phase and therefore their $T_{\text{tr}, \text{H} \rightarrow \text{X}}$ must be properly estimated. Experimental and assessed data are listed in Table 7 and plotted in Figure 5.

Several experimental data were reported for La_2O_3 and Pr_2O_3 [3, 9-11]. The results of La_2O_3 are in excellent agreement except those from Tresvyatkii et al. [9], where results were 60 – 70K lower than other data. In this study, the average value of the experimental transition temperatures excluding the result of Tresvyatkii et al. is taken for the $T_{\text{tr}, \text{H} \rightarrow \text{X}}$ of La_2O_3 . In the case of Pr_2O_3 , the average of all available data is accepted for the $T_{\text{tr}, \text{H} \rightarrow \text{X}}$. Exact same transition temperature of 2443K was reported by Tresvyatkii et al., Shevthenko and Lopato [11] for Ce_2O_3 ,

which is accepted in this study. For Nd_2O_3 , the results of Foex and Traverse [3], and Shevthenko and Lopato [11] are collectively below those of Coutures and Foex [10] and Tresvyatkii et al., by 30 – 40K. In this study, the later [9, 10] were chosen because of the well-established $\text{H} \rightarrow \text{X}$ transition in the binary $\text{La}_2\text{O}_3 - \text{Nd}_2\text{O}_3$ phase diagram by Coutures and Foex.

The transitions of Pm_2O_3 and Eu_2O_3 were investigated by Chikalla et al., [12] Foex and Traverse [3] respectively. The transition temperatures were all fairly aligned with the trend established by available data of the other adjacent RE_2O_3 as seen in Figure 5. Therefore, their experimental data are accepted in this study.

The transition temperature of Sm_2O_3 were reported from 2498K to 2553K by several research groups [3, 9-11]. The average value 2526K is accepted in this study because of generally small discrepancies among all data. It should be noted that the average is supported by the data 2520K from binary $\text{La}_2\text{O}_3 - \text{Sm}_2\text{O}_3$ phase diagram of Coutures and Foex [10].

Regarding Gd_2O_3 , Foex and Traverse [3], and Tresvyatkii et al., [9] agreed lower $T_{\text{tr,H} \rightarrow \text{X}}$ (2613 – 2622K) while Coutures and Foex [10], Shevthenko and Lopato [11] concurrently reported higher values (2641 – 2643K). Because of well determined $\text{H} \rightarrow \text{X}$ transition in the $\text{La}_2\text{O}_3 - \text{Gd}_2\text{O}_3$ phase diagram by Coutures and Foex, present study accepts higher transition temperatures [10, 11].

Mixed $\text{H} \rightarrow \text{X} \rightarrow \text{L}$ transition was observed by Tresvyatkii et al., [9] for Tb_2O_3 and Dy_2O_3 at 2613 – 2643K and 2633K, respectively. On the other hand, discrete $\text{H} \rightarrow \text{X}$ transitions of Tb_2O_3 and Dy_2O_3 were confirmed by Coutures and Foex [10], Shevthenko and Lopato [11], which are accepted in this study.

Heavy RE_2O_3 with smaller ionic radii than the one of Dy_2O_3 melt directly from H phase. Therefore, the $T_{\text{tr,H} \rightarrow \text{X}}$ of Y_2O_3 and $\text{Ho}_2\text{O}_3 - \text{Lu}_2\text{O}_3$ were estimated from the linear relationship established from transition temperature – ionic radii of $\text{La}_2\text{O}_3 - \text{Dy}_2\text{O}_3$ discussed above. Since the ionic radius of Sc_2O_3 is much smaller than Lu_2O_3 , the simple estimation from this linear relationship was not adequately accurate. As the matter of fact, when $T_{\text{tr,H} \rightarrow \text{X}}$ was estimated using

the linear relationship, the resultant $\Delta H_{tr,C \rightarrow L}^\circ$ was too large, so the calculated $\Delta H_{tr,C \rightarrow L}^\circ$ exceeded experimental enthalpy of fusion of Sc_2O_3 reported by Shpil'rain et al., [21]. Therefore, $T_{tr,H \rightarrow X}$ of Sc_2O_3 was calculated using properly estimated $\Delta H_{tr,H \rightarrow X}^\circ$ and $\Delta S_{tr,H \rightarrow X}^\circ$, which will be explained in details in section 6.2.3.

2.5 Temperatures of X→L Phase Transition

The last discrete transition X→L was confirmed to exist in the range $\text{La}_2\text{O}_3 - \text{Dy}_2\text{O}_3$ by various researchers [3, 9-11, 22-27] using TA, DTA and direct melting in crucible methods. Experimental values, hypothetical and assessed results are listed in Table 8 and plotted in Figure 6.

Numerous experimental data [3, 9-11, 23, 27] were reported for the two light RE_2O_3 members La_2O_3 and Pr_2O_3 . The experimental data for La_2O_3 are all $2581 \pm 3\text{K}$. The data of Pr_2O_3 spread between 2533 and 2573K, but it is hard to reject any data because all data were obtained using similar experimental procedures. Therefore, the average values were accepted in this study. Exact the same result 2513K were obtained by Tresvyatkii et al [9] , Shevthenko and Lopato [11] for Ce_2O_3 , which is accepted in this work. Excellent agreement for the transition of Nd_2O_3 is found in the results of Foex and Traverse [3] and Mizuno et al.,[26], while other studies [9-11, 22] show a larger scattering. Result by Mizuno et al. was further supported by their Nd_2O_3 liquidus data of the $\text{Nd}_2\text{O}_3 - \text{Al}_2\text{O}_3$ phase diagram [26], which was accurately reproduced by the assessment of Wu and Pelton [28]. Therefore, an average temperature 2574K from the two studies by Foex and Traverse, and Mizuno et al. is accepted in this study for Nd_2O_3 .

The only result for Pm_2O_3 was reported by Chikalla et al., [12], and showed great consistency with its adjacent RE_2O_3 as shown in Figure 6. Therefore, this result is accepted in this study. The transition temperatures [3, 9-11, 24] are all within $2597 \pm 16\text{K}$. As the reliabilities of all the reported values for Sm_2O_3 are considered as acceptable, the average 2597K is employed in this study. Experimental melting data for Eu_2O_3 was limited to two values reported by Foex and Traverse [3] 2598K, and Mizuno et al., [25] 2633K using TA technique. The average value 2616K is accepted for Eu_2O_3 in this study. Melting temperature of Gd_2O_3 were somewhat scattered from

2665K to 2718K noted in Table 8. Exact the same value 2683K was discovered by both Shevthenko and Lopato [11], and Mizuno et al., which is nearly the average value of all available data. Therefore, 2683K is accepted in this work for Gd₂O₃.

The melting of Tb₂O₃ from X phase was reported at 2673K in all the investigations [3, 9, 11], which is accepted in this work. For Dy₂O₃, Tresvyatkii et al., [9] and Mizuno et al., [29] reported the melting at 2633 and 2643K respectively, which are lower than 2674±1K by Foex and Traverse, Coutures and Foex, and Shevthenko and Lopato [3, 10, 11]. Considering abundant liquidus data in the La₂O₃ – Dy₂O₃ phase diagram reported by Coutures and Foex, the 2674K is accepted in this work.

For the heavy RE₂O₃ with smaller ionic radii than one of Dy₂O₃, their meltings occur directly from H or C phase instead of X. Therefore, the metastable T_{tr,X→L} for Y₂O₃ and Ho₂O₃ – Yb₂O₃, were calculated using the evaluated $\Delta H_{tr,X \rightarrow L}^{\circ}$ and $\Delta S_{tr,X \rightarrow L}^{\circ}$. The details will be discussed in section 6.2.3. For Lu₂O₃ and Sc₂O₃, C phase was retained until melting. The T_{tr,X→L} for Lu₂O₃ was estimated using a linear relationship of T_{tr,X→L} with respect to ionic radii of RE³⁺ for all the assessed and calculated data from La₂O₃ to Yb₂O₃. The simple linear relationship of T_{tr,X→L} was not applied successfully to Sc₂O₃. The T_{tr,X→L} for Sc₂O₃ was estimated using calculated ΔH_{tr}° and ΔS_{tr}° of Sc₂O₃, which will be discussed in section 6.2.3.

2.6 Temperatures of C→H, B→H, H→L and C→L Phase Transition

Although the standard transition sequence of RE₂O₃ is C→B→A→H→X→L, other stable transitions of C→H, B→H, H→L and C→L occur in heavy RE₂O₃, Y₂O₃ and Sc₂O₃.

2.6.1 C→H Phase Transition

The stable phase transition of C→H was observed for heavy RE₂O₃ in the range of Er₂O₃ to Yb₂O₃ and Y₂O₃ by several researchers [9, 11, 30-32]. The experimental data and assessed values in this study are plotted in Figure 7 and listed in Table 9.

The transition of Y_2O_3 reported by Shevthenko and Lopato [11] is 2663K, which is higher than the results of Navrotsky [31] at 2581K, Tresvyatkii et al., [9] at 2623K, and Shpil'rain et al., [32] at 2600K. The $T_{tr,C\rightarrow H}$ by Shpil'rain et al has been widely accepted in literature and show excellent agreement with Navrotsky and Tresvyatkii's DTA results. It should be noted that 2600K was also accepted by Zinkevich [2], while Grobner et al., [30] used 2660K in their assessment of Y – O binary system. Because of supportive evidences from various researchers, 2600K was accepted for $C\rightarrow H$ of Y_2O_3 in this work.

The $C\rightarrow H$ transition of Er_2O_3 , Tm_2O_3 and Yb_2O_3 were determined by many researchers [3, 9-11, 33], and results show large scattering. In the present study, the transitions determined by Shevthenko and Lopato [11] using DTA technique are accepted because they show precise linear relationship between T_{tr} and ionic radii in $Er_2O_3 - Yb_2O_3$ range.

2.6.2 B→H Phase Transition

The $B\rightarrow H$ transition was observed for RE_2O_3 in the range $Tb_2O_3 - Ho_2O_3$ by several researchers [3, 9-11] using TA and DTA methods. Experimental and assessed transition temperatures were plotted in Figure 8 and listed in Table 10.

Tresvyatkii et al., [9], Shevthenko and Lopato [11] reported mixed transitions involving H phase for Gd_2O_3 , but this seems due to slow kinetics. Similar confusing result was reported for Er_2O_3 by Tresvyatkii et al. For Tb_2O_3 , Dy_2O_3 and Ho_2O_3 , Foex and Traverse [3], Coutures and Foex [10] observed combined $B\rightarrow H$ transition using TA technique, while Tresvyatkii et al., Shevthenko and Lopato reported a mixture of multiple transitions involving H phase. Therefore, the results by the groups of Foex [3] and Coutures [10], which are in excellent agreement, are accepted in this study. A precise linear relationship between T_{tr} and ionic radii of RE^{3+} is established, as seen in Figure 8.

2.6.3 H→L Phase Transition

The H→L transition is confirmed to occur from Y_2O_3 – Yb_2O_3 by many researchers [3, 9-11, 30-32] using TA, DTA, drop calorimetry and electric conductivity measurements. Experimental results and assessed values were presented in Table 11 and plotted in Figure 9.

For Y_2O_3 , the melting temperatures from many investigations [3, 9, 11, 32] are between 2683 and 2713K, while the result of Navrotsky [31] is 2655K, which is much lower than the others. In this work, 2703K from Shpil’rain et al., [32] is accepted for the melting of Y_2O_3 . The melting of Ho_2O_3 [3, 9-11] was measured by TA and DTA techniques. In this study, the average value 2686K is accepted because of comparable reliability of the data. For the meltings of Er_2O_3 and Yb_2O_3 , the results of Tresvyatkii et al., [9] show a lower value, therefore excluded in averages for Er_2O_3 and Yb_2O_3 . For Tm_2O_3 , the experimental data were limited to two values reported by Foex and Traverse [3], Shevthenko and Lopato [11]. Therefore, the average of these two works [3, 11] was accepted as recommendation in this work.

2.6.4 C→L Phase Transition

Lu_2O_3 and Sc_2O_3 retain in C structure until their meltings. Shevthenko and Lopato [11] reported the melting at 2783K for Lu_2O_3 and Shpil’rain et al., [32] reported $2782 \pm 20\text{K}$ for Sc_2O_3 .

2.7 Overall View of Phase Transitions

The overall stable phase transformations optimized in this study are shown in Figure 10. Each point represents the selected value after rigorous assessment of all available experimental results in the literature. To present the phase transition clearly, solid lines are used to connect the same phase transition type, and dotted lines show the changes in the phase transition type between adjacent RE_2O_3 . In general, the temperature of the same type of phase transition is increasing with decreasing ionic radii of RE^{3+} (that is, increasing atomic number). In particular, the slope of C→B and B→A transitions with ionic radii are steepest than other transitions.

3. Standard Enthalpy of Formation

The enthalpies of formation of lanthanide sesquioxides (excluding Sc_2O_3 and Y_2O_3) have been critically assessed by Cordfunke and Konings [34] in 2001 by critically evaluating all available literature data until 2000. In this work, original experimental data of all RE_2O_3 , including Sc_2O_3 and Y_2O_3 were collected and critically evaluated again. The best consistent set of ΔH_{298}° was obtained after critical and systematic assessment of available experimental data and rigorous adjustment for consistency with the phase transition. Some of the ΔH_{298}° data earlier than 1950 were not discussed in this work because of inaccuracy due to obsolete experimental techniques and low purity rare earth metals employed, as pointed out by Cordfunke and Konings [32]. The high quality rare earth metals were not available until Dr. Spedding was able to produce them using ion exchange method [35] in the late 1940s. More information about studies prior to 1950 can be found in the study of Cordfunke and Konings.

Generally, the ΔH_{298}° of RE_2O_3 are measured using solution calorimetry and combustion calorimetry. The reaction procedures of the aqueous solution calorimetry are illustrated from Reaction 1 – 4 [32], the dissolution enthalpies from Reaction 1 and Reaction 2 are collected from literature, while the enthalpies of decomposition of H_2O into elemental products in HCl solution with different concentrations were carefully calculated by Cordfunke and Konings [36]. Since the H_2O decomposition enthalpies are extensively studied through history, the values reported by Cordfunke and Konings [36] are used directly without modifications.

Equation 1 $\Delta H_f^\circ \text{RE}_2\text{O}_3 = \Delta H_{r,4}^\circ = (\Delta H_{r,1}^\circ - \Delta H_{r,2}^\circ) + \Delta H_{r,3}^\circ$.

For combustion calorimetry, ΔH_{298}° is measured directly by reacting pure metal and oxygen. The combustion reaction is illustrated below:

The present study used the similar analysis technique for the evaluation of ΔH_{298}° of RE_2O_3 as Cordfunke and Konings [34] did. In the most of cases, the differences between the optimized data in this study and the assessed data by Cordfunke and Konings on lanthanide sesquioxides are smaller than few kJ/mol except Ce_2O_3 . In addition, in this study, the ΔH_{298}° of Sc_2O_3 , Y_2O_3 and Gd_2O_3 (C form) were optimized which were not available in the study by Cordfunke and Konings. It should be noted that Zinkevich [2] adopted the assessed values of Cordfunke and Konings without any modification. The detailed discussions about the evaluation of the enthalpy in this study are below.

3.1 Standard Enthalpy of Formation of Sc_2O_3 and Y_2O_3

3.1.1 The ΔH_{298}° of C – Sc_2O_3

The ΔH_{298}° of C – Sc_2O_3 was determined by Mah [37] using combustion calorimetry. Huber used combustion calorimetry in his first study [38] with Holley in 1962 and both solution and combustion techniques in the second study [39] with Fitzgibbon in 1963. The results reported by both research groups [37-39] were listed in Table 12. Mah analyzed the starting metal and final product of combustion experiment and confirmed the non – metallic impurities in the starting metallic sample and crucible materials in the product, which caused uncertainty in enthalpy data. Huber and Holley also reported the usage of relatively impure Sc metal and contamination of product by non – Sc_2O_3 . In Huber's second study with Fitzgibbon, the impurities of initial metal sample and final product were corrected for combustion experiment, while the result from solution calorimetry was composed without known states of impurities. Therefore, combustion result from Huber and Fitzgibbon is accepted in this study. It should be also noted that after the experiment of Huber and Fitzgibbon, Mah conducted a trail combustion experiment again using sample supplied by Huber and a Sc_2O_3 crucible, a similar result to Huber and Fitzgibbon was obtained [36]. Furthermore, Huber's second combustion value was also accepted in the assessment by Leonidov et al., [40] of thermodynamic properties of Sc_2O_3 .

3.1.2 The ΔH_{298}° of C – Y_2O_3

The ΔH_{298}° of $C - Y_2O_3$ was determined by Huber and Holley [41], Lavut and Chelovskaya [42] using combustion calorimetry technique. Wang et al., [43] and Morss et al., [44] measured the enthalpy of Y metal and Y_2O_3 in 1M HCl aqueous solution, respectively. All the available experimental data and selected values were presented in Table 12.

Huber and Holley [41] made correction for the impurities in starting material Y and product Y_2O_3 to get ΔH_{298}° . Lavut and Chelovskaya [42] discussed the combustion reaction in the study by Huber and Holley was incomplete by judging the color of the final oxides (light tan color due to deficiency of oxygen). They carefully reinvestigated using combustion calorimetry and obtained $-1919.4 \pm 2.8 \text{ kJ/mol}$ [42], which was about 14 kJ/mol more negative than the result of Huber and Holley.

Wang et al., [43] measured the dissolution enthalpy of Y metal in 1M HCl solution and estimated ΔH_{298}° of Y_2O_3 . Morss et al., [44] determined the ΔH_{298}° of Y_2O_3 by combining their dissolution enthalpy of Y_2O_3 oxide in 1M HCl and Wang's experimental result for Y. The starting materials used in the studies of Morss and Wang were higher in purity than those of Huber and Lavut [41, 42]. It is noted final result ΔH_{298}° from Morss et al., is more negative than both combustion values [41, 42] by 10 – 30 kJ/mol, but very close to the estimation in the study of Wang et al., as shown in Table 12. Considering the high purity materials used by Morss et al., and Wang et al., the combined result reported by Morss et al. is selected in this study.

3.2 Standard Enthalpy of Formation for Light RE_2O_3

3.2.1 The ΔH_{298}° of $A - La_2O_3$

The ΔH_{298}° of $A - La_2O_3$ was measured by Huber and Holley [45] using combustion calorimetry, Fitzgibbon and Holley [46] and Gvelesiani and Yashvili [47] using solution calorimetry. All the experimental results were listed in Table 13.

Prior to the study of Huber and Holley [45], the measurements from literature had large discrepancies mainly due to the usage of impure La metal, therefore those measurements were not

considered in this study. Fitzgibbon and Holley [46], Gvelesiani and Yashvili [47] measured the dissolution enthalpy of La and La₂O₃ in aqueous solution calorimeter. However, Cordfunke and Konings [34] reported that the enthalpies of La metal dissolution in both studies have issues of incomplete dissolution. Therefore, the result of La from Merli et al., [48] and the result of La₂O₃ from Fitzgibbon and Holley, and Gvelesiani and Yashvili were combined to obtain ΔH_{298}° of La₂O₃ in this study. That is the average of revised values.

3.2.2 The ΔH_{298}° of A – Ce₂O₃

ΔH_{298}° of Ce₂O₃ was measured by combining the combustion heat of Ce₂O₃ to CeO₂ and Ce to CeO₂ because burning Ce metal always resulted in CeO₂ instead of Ce₂O₃ [49]. The reaction scheme of the combustion calorimetry for Ce₂O₃ was shown below [50]:

$$\Delta H_{298}^{\circ} \text{ Ce}_2\text{O}_3 = \Delta H_{r,3}^{\circ} = -(\Delta H_{r,1}^{\circ} - \Delta H_{r,2}^{\circ})$$

All the results of Ce₂O₃ were listed in Table 13. Heats of Reaction 5 were measured by Kuznetsov et al., [49], Mah [50], Baker and Holley [51]. They further combined their results of Reaction 5 with the result of Reaction 6 by Huber and Holley [52] to obtain ΔH_{298}° of Ce₂O₃. The relatively large differences between the three results may be due to carbon and hydrogen impurities [53] or slight oxidation in the starting Ce₂O₃ materials [34, 51].

Recently, Huntelaar et al., [53] using solution calorimetry and Putnam et al., [54] using transposed temperature drop calorimetry measured the ΔH_{298}° of Ce₂O₃. Huntelaar et al., performed five measurements on dissolution enthalpy of Ce₂O₃ in 0.25M HCl and combined with the dissolution enthalpy of Ce from Spedding and Miller [55] to get ΔH_{298}° . Some CeO₂ debris were found after their experiments, but correction was made accordingly on the final ΔH_{298}° . Putnam et al., [52] used the same preparation and characterization methods to the one of Huntelaar

et al. That is, both studies used the same high purity Ce_2O_3 samples for experiments. In this study, the average $-1809.45 \pm 3.3 \text{ kJ/mol}$ of these two studies [53, 54] is accepted for ΔH_{298}° of Ce_2O_3 .

3.2.3 The ΔH_{298}° of A – Pr_2O_3

The limited ΔH_{298}° of Pr_2O_3 were reported by Stubblefield et al., [56] and Fitzgibbon et al., [57] using solution calorimetry. All the available experimental data and the recommended values were shown in Table 13.

In the study of Stubblefield et al., [56], the heat of Pr_2O_3 dissolution in 6M HNO_3 was measured and combined with Pr metal dissolution enthalpy in 1.2M HCl measured by Spedding and Flynn [58] to obtain the final ΔH_{298}° . Later in 1969, Stubblefield [59] conducted more measurements using adiabatic solution calorimeter of enthalpy of dissolving rare earth metals in acidic solutions with various concentrations (6M HNO_3 , 1M HCl and 6M HCl). It is found that the dissolution enthalpy of Pr metal in 6M HNO_3 [59] was around 300kJ/mol more negative than the result of Spedding and Flynn in 1.2M HCl . Fitzgibbon explained in his study that dissolution of Pr metal in HNO_3 solution might not be desirable because the hydrogen produced during reaction could reduce the acid. Fitzgibbon conducted extensive measurements on dissolution of Pr and Pr_2O_3 in different acidic solutions, including 2M HCl , 2M HNO_3 and 6M HNO_3 . The result of rigorous study by Fitzgibbon et al., [57] is accepted in this work.

3.2.4 The ΔH_{298}° of A – Nd_2O_3

Since Nd_2O_3 is one of the widely used rare earth sesquioxides, experimental ΔH_{298}° were reported as early as 1900s. After 1950, data with acceptable accuracy were reported by Huber and Holley [60] and Spedding et al., [61] using combustion calorimetry, and Fitzgibbon et al., [62], Yashvili and Gvelesiani [63], Morss and Haar [64] and Monaenkova et al., [65] using solution calorimetry. All the experimental and selected values are shown in Table 13.

For combustion experiments by Huber and Holley [60], the starting materials were carefully characterized and the completeness of the combustion experiment was nearly 100%.

Extra oxygen was found in the final products after experiments, but corrected for the final ΔH_{298}° . In comparison with the work by Huber and Holley, the result obtained using combustion method from Spedding et al., [61] was more positive and considered as less reliable due to incompleteness of the combustion and mass loss of the crucible.

Regarding the results from solution calorimetry, Fitzgibbon et al., [62] measured dissolution enthalpies of Nd_2O_3 in 2M and 4.36M HCl solutions. They reported final ΔH_{298}° for Nd_2O_3 by combining their experimental data and the data on Nd metal dissolution by Stuve [66]. It is observed that ΔH_{298}° from Fitzgibbon's group showed excellent agreement with that of Huber and Holley [60] from combustion method. For further comparison, the experimental result by Fitzgibbon et al., of Nd_2O_3 was combined in this study with the Nd dissolution enthalpy by Merli et al., [48] to obtain ΔH_{298}° for Nd_2O_3 . This result is also in good agreement with the result of Huber and Holley.

Yashvili and Gvelesiani [63] reported the dissolution enthalpy of Nd_2O_3 in 6M HCl. Their result was combined with available dissolution enthalpy of Nd by Merli et al., [48] - $1831.70 \pm 7.80 \text{ kJ/mol}$, which was significantly more negative than the other results. Popova and Monaenkova [67] measured the dissolution enthalpy of Nd metal and Nd_2O_3 in 2.19M HCl solution as $-686.77.85 \pm 1.17 \text{ kJ/mol}$ and $-434.11 \pm 0.87 \text{ kJ/mol}$, respectively. These give the $\Delta H_{298}^{\circ} = -1796.8 \pm 1.9 \text{ kJ/mol}$ [67], which is somewhat agreeable to the less accurate value from Spedding et al., [61]. In this study, a very close value -1808.81 kJ/mol of the studies [60, 62] is accepted for ΔH_{298}° for Nd_2O_3 .

3.3 Standard Enthalpy of Formation for Middle RE_2O_3

3.3.1 The ΔH_{298}° of C and B – Sm_2O_3

The ΔH_{298}° of C – Sm_2O_3 was measured by Gvelesiani and Yashvili [47], Baker and Pavone [68] using solution calorimetry. The ΔH_{298}° of B – Sm_2O_3 was measured by Huber et al., [69] and Spedding et al., [61] using combustion calorimetry, Gvelesiani and Yashvili [47], Hennig and

Oppermann [70] using solution calorimetry. Baker and Pavone [68] studied the ΔH_{298}° of B form using both techniques. All the experimental data and selected values are listed in Table 14.

In combustion calorimetry studies, Huber et al., [69] obtained ΔH_{298}° of B – Sm_2O_3 as $-1815.40 \pm 2.01 \text{ kJ/mol}$, which was the result after careful correction of impurity compositions. Spedding et al., [61] found ΔH_{298}° of B – Sm_2O_3 as -1777.3 kJ/mol , which was significantly more positive than the other literature results [47, 68-70]. The large discrepancy might be due to the incompleteness of combustion of Sm in the study of Spedding et al. The ΔH_{298}° of B – Sm_2O_3 obtained by Baker and Pavone [68] is -1824 kJ/mol from both combustion and solution calorimetry.

The dissolution enthalpy of B – Sm_2O_3 in 4M HCl solution obtained by Hennig and Oppermann [70] was combined with dissolution enthalpy of Sm metal by Baker and Pavone [68] to obtain $\Delta H_{298}^{\circ} = -1824.67 \pm 7.99 \text{ kJ/mol}$ as seen in the study of Cordfunke and Konings [34]. This value was in excellent agreement with Baker and Pavone. Though Cordfunke and Konings ignored the uncertainties might be introduced by combining results measured in HCl solutions with different concentrations. Gvelesiani et al., [47] conducted experiments on both B and C forms and found ΔH_{298}° of C form $-1826.32 \pm 7.10 \text{ kJ/mol}$ was more positive in value than B form $-1832.17 \pm 7.95 \text{ kJ/mol}$. This observation was proven not true by Baker and Pavone after their experiments. It is also found in this work that the assessed ΔH_{298}° of the other middle RE_2O_3 (Eu_2O_3 and Gd_2O_3) all have more negative values of C form indicating C form is more stable than B form. Extensive experiments were conducted by Baker and Pavone using both combustion and solution calorimetry. ΔH_{298}° of $-1824.18 \pm 2.64 \text{ kJ/mol}$ and $-1823.64 \pm 1.90 \text{ kJ/mol}$ for B – Sm_2O_3 , and $-1827.41 \pm 3.05 \text{ kJ/mol}$ for C form were obtained. Impurities of starting materials were taken into consideration and corrected for the final ΔH_{298}° .

In this study, the ΔH_{298}° of both B and C forms were selected from Baker and Pavone [68] and modified within the uncertainty range to accord with $T_{tr,C \rightarrow B}$ at 1153K (section 2.1) and the trends of $\Delta H_{tr,C \rightarrow B}^{\circ}$ and $\Delta S_{tr,C \rightarrow B}^{\circ}$ (section 6.2.1). The optimized ΔH_{298}° of C and B forms of Sm_2O_3 were -1827.19 kJ/mol and -1822.60 kJ/mol , respectively.

3.3.2 The ΔH_{298}° of C and B – Eu_2O_3

The ΔH_{298}° of C and B form Eu_2O_3 were investigated by Huber et al., [71] and Fitzgibbon et al., [16] using both combustion and solution calorimetry. Yashvili and Gvelesiani [63], Hennig and Oppermann [72] performed experiments on B form, and Stuve [73] studied C form using solution calorimetry technique. All the experimental and selected data were shown in Table 14.

Huber et al., [71] reported ΔH_{298}° of B form $-1648.08 \pm 3.77 \text{ kJ/mol}$ from several combustion experiments. In his solution calorimetry study, the $\Delta H_{tr,C \rightarrow B}^{\circ}$ was determined to be $17.99 \pm 2.51 \text{ kJ/mol}$ by measuring the enthalpy difference between dissolution enthalpy of B and C form of Eu_2O_3 . Therefore, the ΔH_{298}° of C form $-1630.09 \pm 4.60 \text{ kJ/mol}$ was calculated using previous ΔH_{298}° of B – Eu_2O_3 from combustion method and the obtained $\Delta H_{tr,C \rightarrow B}^{\circ}$ Stuve [70] determined $\Delta H_{298}^{\circ} = -1619.08 \pm 5.02 \text{ kJ/mol}$ for C – Eu_2O_3 using solution calorimetry. The value was significantly more positive than other values for C – Eu_2O_3 as shown in Table 14. Stuve discussed that his result must be considered provisional as relatively impure Eu metal used and unknown sources of uncertainties during experimental procedures. Yashvili et al., [63] determined $\Delta H_{298}^{\circ} = -1725.48 \pm 5.10 \text{ kJ/mol}$ for B – Eu_2O_3 using solution calorimetry. Their result was significantly more negative than the values for B form reported by others [16, 71, 72] as shown in Table 14. The purity of the experimental starting materials in the study of Yashvili et al., was uncertain because the composition was not described in their work. Therefore, Yashvili's study was not considered in this work. Hennig and Oppermann [72] measured the dissolution enthalpy of several Eu compounds including B form of Eu_2O_3 . The Eu_2O_3 dissolution enthalpy was combined with the dissolution of Eu by Stuve [70] and Fitzgibbon et al., [14] to obtain $-1686.22 \pm 5.27 \text{ kJ/mol}$ and $-1730.48 \pm 6.11 \text{ kJ/mol}$, which were too negative. Consequently, the result of Hennig and Oppermann was not considered in this work.

The most reliable measurements of the ΔH_{298}° of both C and B forms of Eu_2O_3 were obtained by Fitzgibbon et al., [16] after the first paper with Huber et al., [71]. The Eu metal used in the experiment was carefully analyzed for impurities. Numerous experiments on Eu_2O_3 and Eu metal dissolution enthalpies in 2M, 4M and 6M HCl and HNO_3 acid solution were performed to

increase accuracy. $\Delta H_{298}^{\circ} = -1651.42 \pm 3.35 \text{ kJ/mol}$ for B – Eu_2O_3 was the average results from both solution and combustion calorimetry. $\Delta H_{298}^{\circ} = -1661.10 \pm 3.76 \text{ kJ/mol}$ for C – Eu_2O_3 was obtained using solely solution calorimetry. Fitzgibbon et al., [16] also compared that the dissolution enthalpy of Eu by Stubblefield et al., [74] is about 20 to 40 kJ/mol more positive than their data.

In this study, ΔH_{298}° Fitzgibbon et al., [16] were slightly modified to accommodate $T_{tr,C \rightarrow B}$ at 1348K (section 2.1) and the trend of $\Delta H_{tr,C \rightarrow B}^{\circ}$ and $\Delta S_{tr,C \rightarrow B}^{\circ}$ (section 6.2.1). The optimized values of C and B forms of Eu_2O_3 were -1657.95 kJ/mol and -1653.45 kJ/mol, respectively.

3.3.3 The ΔH_{298}° of C and B – Gd_2O_3

The ΔH_{298}° data for B – Gd_2O_3 were reported by Huber and Holley [75] and Spedding et al., [61] using combustion calorimetry, and Yashvili and Gvelesiani [63] using solution calorimetry. Huber and Holley [75] reported $\Delta H_{298}^{\circ} = -1815.7 \pm 3.6 \text{ kJ/mol}$ as shown in Table 14 for Gd_2O_3 by burning Gd metal supplied from Dr. Spedding's lab. Huber and Holley commented that the analytical characterization techniques were limited at that time, thus the chemical state of the impurities remained uncertain. The impurities, including C, N, Ca, O and H, were assumed to form compounds with Gd and potentially reduced purity level by 2.5%. The final ΔH_{298}° was corrected by Huber for those assumed impurities. Spedding et al., obtained $\Delta H_{298}^{\circ} = -1782.2 \text{ kJ/mol}$ using combustion method. Similar to the other results of Lanthanide sesquioxides that reported by Spedding et al., [61], the ΔH_{298}° was much more positive than the other literature values [63, 75]. Spedding et al., commented the reasons might be incompleteness of combustion and limitation of the analytical techniques. Yashvili and Gvelesiani obtained $\Delta H_{298}^{\circ} = -1824.22 \pm 1.80 \text{ kJ/mol}$ for B form Gd_2O_3 using solution calorimetry.

Because of similar physical and chemical properties of lanthanide sesquioxides, roughly linear decreasing trend of ΔH_{298}° with decreasing of ionic radii can be obtained. Therefore, ΔH_{298}° of B – Gd_2O_3 should be smaller than B – Sm_2O_3 . In this study, the result by Yashvili and Gvelesiani [63] fitted in the trend, therefore, accepted for ΔH_{298}° of B – Sm_2O_3 .

The ΔH_{298}° of C – Gd₂O₃ is not available in the literature. The value was estimated by considering $T_{tr,C \rightarrow B}$ at 1561K (section 2.1), the trend of $\Delta H_{tr,C \rightarrow B}^\circ$ and $\Delta S_{tr,C \rightarrow B}^\circ$ (section 6.2.1). The optimized ΔH_{298}° were -1830.93kJ/mol and -1825.19kJ/mol for C and B form Gd₂O₃, respectively. All the experimental and selected data were shown in Table 14.

3.4 Standard Enthalpy of Formation for Heavy RE₂O₃

The ΔH_{298}° for C – Tb₂O₃ was studied by Stubblefield and Eick [76], Fitzgibbon and Holley [77] using solution calorimetry. It is important to note that terbium oxides consist of Tb₂O₃ and non – stoichiometric oxides, which may increase the difficulties of experiments. All the experimental and selected data were shown in Table 15.

Stubblefield and Eick [76] investigated the solution enthalpies of several stable Tb oxides, including Tb₂O₃, in 6M HNO₃ solution. However, they were unable to obtain the dissolution enthalpy of Tb metal. In order to calculate ΔH_{298}° , they determined the missing enthalpy by linear interpolating enthalpy measurements on various rare earth metals from Spedding and Flynn [58]. The resultant ΔH_{298}° reported by Stubblefield and Eick was -1827.57±8.37kJ/mol. In the more recent assessment paper, Cordfunke and Konings [34] combined their previous assessed enthalpy of metal dissolution with the result of Stubblefield and Eick to yield a more negative ΔH_{298}° - 1864.5±8.4kJ/mol.

Fitzgibbon and Holley [77] measured the solution enthalpy of Tb in 1M HCl and the solution enthalpies of a series terbium oxides in 6M HNO₃ solution. According to Fitzgibbon and Holley [77], HNO₃ solution could not be used to dissolve Tb metal because of unwanted reduction of the acid, and HCl solution could not be used on Tb oxides because of undesired oxidation of the acid. It was more problematic that dissolving Tb₂O₃ in HNO₃ had unacceptably slow kinetics for accurate measurements [77]. Therefore, the final result -1865.23±7.53kJ/mol was extrapolated from results of a series of terbium oxides measurements [77], which is in good agreement with the re – evaluated value by Cordfunke and Konings [34]. Therefore, the result of Fitzgibbon and Holley is accepted in this study.

3.4.1 The ΔH_{298}° of C – Dy₂O₃

The ΔH_{298}° of C – Dy₂O₃ was measured by Huber et al., [78] using combustion calorimetry in the first investigation, and both combustion and solution calorimetry techniques in the second study [79]. In the first study, relatively impure Dy metal was used to obtain -1865.39±3.89kJ/mol as shown in Table 15. In the second study, purer samples were employed in combustion method to get -1863.14±4.18kJ/mol. Two dissolution enthalpies of Dy metal and Dy₂O₃ were determined in 4M HCl. The result from solution technique -1863.97±6.69KJ/mol showed an excellent agreement with the second combustion calorimetry result. The average -1863.22±3.56kJ/mol of Huber et al., in their second study [79] was accepted in this work, which was also accepted by Cordfunke and Konings [34].

3.4.2 The ΔH_{298}° of C – Ho₂O₃

Combustion and solution calorimetry were employed by Huber et al., [80] and Morss et al., [44], respectively, to study the ΔH_{298}° of C – Ho₂O₃. Huber et al., obtained the ΔH_{298}° - 1880.92±4.81kJ/mol (Table 15) after careful correction of impurity contribution. Morss et al., only measured the enthalpy of Ho₂O₃ in 4M HCl solution and evaluated dissolution enthalpy of Ho from literature. Morss et al., commented the Ho metal dissolution enthalpy from Stuve [81] had substantial uncertainty therefore neglected from their study. Bettonville et al., [82] reported Ho metal dissolution enthalpy in 1M HCl solution. Morss et al., corrected the result from Bettonville et al., to a dissolution enthalpy for 4M HCl. The resultant ΔH_{298}° was -1887.3±13.7kJ/mol. Cordfunke and Konings [34] re – evaluated the dissolution enthalpy of Ho₂O₃ from Morss et al., and the enthalpy of Ho metal from Stuve to yield -1885.7±7.3kJ/mol. In this study, because of uncertainties involved in the study by Stuve, ΔH_{298}° is optimized to be -1884.11±9.26kJ/mol, which is the average of the result of Huber et al., and the result of Moss et al.

3.4.3 The ΔH_{298}° of C – Er₂O₃

The ΔH_{298}° of C – Er₂O₃ was determined by Spedding et al., [61] and Huber et al., [83]

using combustion calorimetry, and Morss et al., [44], Montgomery and Stuve [84] using solution technique. In the study of Huber et al., 0.1% impurities were found after carefully analyzing the starting metal and corrected in ΔH_{298}° -1897.82 \pm 1.88kJ/mol. A few years later, Spedding et al., reported the ΔH_{298}° = -1762.84kJ/mol, which was much more positive than other results reported in literature as shown in Table 15, therefore not taken into account in this study. Spedding et al., commented the reason of large discrepancy might due to incompleteness of the combustion reaction, unwanted participation of crucible materials in reaction and limitation of analysis on non – metallic impurities.

Montgomery and Stuve [84] studied the dissolution enthalpy of Er₂O₃ in 1.468M HCl and obtained -370.62 \pm 3.68kJ/mol. When their result was combined with the dissolution enthalpy of Er by Spedding and Flynn [58], Bommer and Hohmann [85], two values - 1815.74 \pm 3.68kJ/mol and -1847.63 \pm 3.68KJ/mol were obtained, respectively. Fuger et al., [86] discussed these two combined results were not sufficiently exothermic, therefore they re-investigated Er dissolution enthalpy in 1.428M HCl solution and found -705.6 \pm 1.7kJ/mol. Combining the result of Fuger et al., and Montgomery and Stuve can produce ΔH_{298}° -1898.19 \pm 7.08kJ/mol. In 1990s, Morss et al., [44] measured the dissolution enthalpy of Er₂O₃ in 1.40M HCl to be -364.6 \pm 3.0kJ/mol. When this result is combined with the result of Fuger et al., [83], ΔH_{298}° -1904.21 \pm 6.40kJ/mol as shown in Table 15. The accepted ΔH_{298}° = -1900.07kJ/mol of Er₂O₃ is the average of the results from Huber et al., [83], and the combined results involving the study of Fuger et al.

3.4.4 The ΔH_{298}° of C – Tm₂O₃

The ΔH_{298}° of C – Tm₂O₃ was determined by Huber and Holley [87] using combustion calorimetry. Huber reported the metal sample used containing 1.27% and 1.55% impurities and the completeness of the combustion reactions varied from 88.67% to 99.67%. Two results - 1894.8 \pm 8.3kJ/mol and -1884.3 \pm 7.9kJ/mol were obtained from the two samples after impurity corrections and resulted the average -1888.66 \pm 5.86kJ/mol as shown in Table 15. This average result is accepted in this study.

3.4.5 The ΔH_{298}° of C – Yb₂O₃ and Lu₂O₃

Limited data were available in the literature for both Yb₂O₃ and Lu₂O₃. The ΔH_{298}° of these two RE₂O₃ were measured by Huber et al., [78, 88] using combustion calorimetry. The starting materials were carefully analyzed as usual as their other studies. The results were -1814.52±2.22kJ/mol and -1878.20±7.53kJ/mol for Yb₂O₃ and Lu₂O₃ respectively. Both of the values are accepted.

3.5 Summary of ΔH_{298}° and Trend

The optimized or accepted ΔH_{298}° of RE₂O₃ are plotted against ionic radii of RE³⁺ in the part (a) of Figure 11, and all experimental data are plotted in part (b). As can be seen in Figure 11(b), there is significant scattering in existing data, but the optimized data in Figure 11 (a) shows clear trend. The typical Lanthanide irregularities are clearly observed for Eu₂O₃ and Yb₂O₃ as shown in part(b). The Eu and Yb elements, which have half-filled and full-filled f-orbitals, are the only divalent crystalline metals in the lanthanide series. The correlation of these irregular thermodynamic properties were well studied by Nugent et al., [89], which introduced the trivalent – divalent transition energy $\Delta E(M)$. The ΔH_{298}° of these RE₂O₃ (excluding Eu₂O₃ and Yb₂O₃) almost linearly decrease with decreasing ionic radii, and the trend can be roughly linearly extended to even Gd₂O₃ with C polymorph. The ΔH_{298}° for C – Pm₂O₃ was therefore estimated from the linearity between Gd₂O₃ and Sm₂O₃ because no experimental data were available in literature.

4. Standard Entropy of RE₂O₃

Low temperature C_p data are generally used to calculate standard entropy, S_{298}° . It is interesting to find out that the experimental low temperature (below 298K) C_p of RE₂O₃ typically show thermal anomaly peaks usually around 10K. According to Justice et al.,[90-94], who extensively studied the low temperature C_p of RE₂O₃, mentioned there are three contributions in C_p to be considered for the calculation of S_{298}° : lattice contribution, magnetics contribution (both antiferro – , or ferro – magnetic and para-magnetic contributions), and ground state degeneracy

contribution. The magnetic contributions by antiferro – or ferro – magnetics appeared as “cooperative anomaly” and that of para – magnetics appeared as “Schottky anomaly”, according to Justice et al. They also analyzed the crystalline field level of each RE_2O_3 and proposed the method to calculate ground state degeneracy contribution. In the present study, we followed the same approach as Justice et al., proposed to calculate the S_{298}° of each RE_2O_3 .

Several rare earth sesquioxides, namely Sc_2O_3 ($3p^6$), Y_2O_3 ($4p^6$), La_2O_3 ($4d^{10}$), Eu_2O_3 ($4f^7$) and Lu_2O_3 ($4f^{14}$), are excluded from the Schottky effect because of absence or lack of unfilled f orbitals, which are the sources of paramagnetic properties.

Justice et al., [90-94] extensively investigated low temperature heat capacity values for (1) A forms of La_2O_3 , Pr_2O_3 , Ce_2O_3 , and Nd_2O_3 and (2) C forms of Gd_2O_3 , Yb_2O_3 , Dy_2O_3 , Ho_2O_3 , Er_2O_3 , Tm_2O_3 and Lu_2O_3 , and (3) B form of Sm_2O_3 from around 5K to 350K. Data for Pm_2O_3 and Tb_2O_3 were not available in literature. In the study of Justice et al., the contribution of magnetic ordering was evaluated from experimental low temperature C_p data by removing lattice contribution. Then, the theoretical magnetic contributions to S_{298}° and lattice contribution to S_{298}° were calculated. In the calculation of lattice contribution, the Debye T^3 approach was of course counted in to calculate the lattice C_p below lowest experimental temperature to 0 K. Then, ground state degeneracy was also added in to calculate total S_{298}° . When the dissociation of lattice contribution and magnetic contribution from experimentally measured C_p data, sometime it was difficult to distinguish each contribution clearly. Therefore, Justices et al., used the standard lattice contribution from La_2O_3 without any magnetism as the lattice C_p of all light RE_2O_3 (A form) to evaluate the magnetic contribution from experimentally observed C_p data. Similarly, they used the lattice C_p of Gd_2O_3 (100 to 298 K) and C_p of Yb_2O_3 (below 100 K) as standard lattice contribution of heavy RE_2O_3 (C form) and obtained the magnetic contribution. Although Lu_2O_3 without any magnetism might be used for lattice C_p of C phase, Justice et al., pointed out the significant lanthanide contractions in Lu_2O_3 which might change the lattice contribution by tens of % from other heavy RE_2O_3 . On the other hand, the experimentally measured C_p of Gd_2O_3 and Yb_2O_3 have very small magnetic contribution, so the lattice contribution can be easily approximated from the experimental data. The contribution of ground state degeneracy was calculated as $2R\ln(\text{number of degeneracy})$ where number of degeneracy was given by Justice et al.

In this work, all available data from the literature were critically reviewed and the standard entropies were evaluated using the same method as Justice et al., suggested. In the assessment process, it was found that the studies of Justice et al., [90-94] were the most consistent and completed, so their low temperature C_p data were used most often in this study to calculate the standard entropy values. Experimental data were not available for all the RE_2O_3 . Low temperature heat capacities for C – Sm_2O_3 and B – Gd_2O_3 were not measured, but estimated by Lyutsareva [17] using spectral data. The standard entropy of Pm_2O_3 was calculated in this work using properties of its adjacent RE_2O_3 . For Tb_2O_3 , magnetic properties measured by Hill [95] were used with the approach by Justice et al., [92] to estimate the S_{298}° . All the reported, evaluated and estimated S_{298}° are listed in Table 17. The available low temperature C_p data are plotted together with high temperature C_p data in Figure 13 to Figure 31. The details of the S_{298}° analysis are given below for each RE_2O_3 .

4.1 Standard Entropy of C – Y_2O_3 and C – Sc_2O_3

The low temperature heat capacities for calculating S_{298}° of cubic Y_2O_3 were measured by Goldstein et al., [96] and Gavrichev et al., [97] in the temperature ranges 16 – 300K and 14 – 300K. No trace of thermal anomalies was observed in the experimental ranges from both studies. Using the Debye – like method to extrapolate data below the experimental temperature limits, Goldstein et al., and Gavrichev et al., obtained exactly the same $S_{298}^\circ = 98.96\text{J/mol}\cdot\text{K}$. In this work, 99.13J/mol·K was obtained from the integration of experimental data from the both studies.

Similar to Y_2O_3 , thermal anomalies were not observed in the low temperature heat capacity data of cubic Sc_2O_3 . Weller and King [98] calculated $S_{298}^\circ = 76.99\text{J/mol}\cdot\text{K}$ by adding the integration of C_p from 50 – 298K and Debye – like extrapolation below 50K. Using the same method and the experimental data from Weller and King, 76.60J/mol·K was obtained in this work.

4.2 Standard Entropy of Light RE_2O_3

4.2.1 The S_{298}° of A – La_2O_3

The low temperature heat capacities of A form of La_2O_3 were measured by Justice and Westrum [92] using an adiabatic calorimeter, and Goldstein et al., [96] and King et al., [99] using Nernst vacuum calorimeter. The measurements by Justice and Westrum, Goldstein et al., and King et al., ranged from 5 – 350K, 16 – 300K and 50 – 298K respectively. Since La_2O_3 is one of the sesquioxides without the thermal anomaly, Debye T^3 extrapolation can be used directly to find out data below experimental limits. Using the data from Justice and Westrum, the standard entropy was found 127.24J/mol·K in this study. This value is in excellent agreement with Goldstein's 127.95 ± 0.29 J/mol·K and Justice's 127.32J/mol·K. A little higher value 128.57 ± 0.84 J/mol·K was obtained by King et al.

4.2.2 The S_{298}° of A – Ce_2O_3

The low temperature heat capacities of Ce_2O_3 for calculating of the S_{298}° were investigated by Justice and Westrum [90] in the temperature range between 5 and 350K, Huntelaar et al., [53] at 3 – 420K, Weller and King [98] at 51 – 300K. Ce_2O_3 is one of the non – stoichiometric oxides in the RE_2O_3 series, therefore, pure Ce_2O_3 is very difficult to obtain for experiments. Extra oxygen composition is observed in many experiments.

In the study of Weller and king [98], the starting material Ce_2O_3 contained significant amount of impurities and led to a non – stoichiometric $\text{Ce}_2\text{O}_{3.33}$. Since their measurements started from 50K, the cooperative transition event below 50K was not included. Therefore, the $S_{298}^{\circ} = 150.62 \pm 4.18$ J/mol·K from Weller and King were not taken into consideration in this work.

In the study of Justice and Westrum [90], the starting material Ce_2O_3 was prepared by carbon reduction of pure cerium dioxide and contained 3.4 wt% of impurities. The low temperature heat capacity data showed a sharp prominent feature at 8.5K indicating a cooperative anomaly effect [90]. Because the cooperative anomaly was large, the Schottky effect was hindered and needed to be accounted for in calculation of S_{298}° [90]. The experimentally evaluated entropy from 5 – 298K covering the sharp peak at 8.5K, the Debye – like extrapolation to 0K and the degeneracy

contribution below 5K were summed $S_{298}^{\circ} = 148.11\text{J/mol}\cdot\text{K}$ [90]. A series of thermodynamic properties of Ce_2O_3 were studied by Huntelaar et al., [53]. They produced Ce_2O_3 sample by reduction from CeO_2 and about 1 wt% impurities [53] were contained in the Ce_2O_3 sample. A sharp antiferromagnetic transition was detected at 5.7K, which was lower than 8.5K from Justice and Westrum. A polynomial function was used by Huntelaar et al., to fit the data from 0 – 5K to interpret the heat capacities below experimental limit 3K. As the result, Huntelaar et al., calculated the $S_{298}^{\circ} = 148.91 \pm 0.40\text{J/mol}\cdot\text{K}$, which was comparable to the result of Justice and Westrum $148.11\text{J/mol}\cdot\text{K}$. In the present study, the result of Huntelaar et al., were re – evaluated to obtain $S_{298}^{\circ} = 148.87\text{J/mol}\cdot\text{K}$ for Ce_2O_3 .

4.2.3 The S_{298}° of A – Pr_2O_3

The only source of the low temperature C_p data of Pr_2O_3 is the personal communication between Gruber et al., and Lutsareva [100] in 1997. The low temperature C_p data from 5 to 300K are inconsistent with the high temperature C_p data from Pankratz and Kelley [101]. Gruber et al., adjusted the original low temperature C_p data to estimate the final S_{298}° $152.73\text{J/mol}\cdot\text{K}$ of Pr_2O_3 . To validate the reliability of the result of Gruber et al., we estimated S_{298}° of Pr_2O_3 as the average of S_{298}° Ce_2O_3 and Nd_2O_3 . The average value was $153.83\text{J/mol}\cdot\text{K}$, which is very close to the S_{298}° reported by Gruber et al. The result of Gruber et al. is used in this study for Pr_2O_3 .

4.2.4 The S_{298}° of A – Nd_2O_3

The low temperature heat capacities of Nd_2O_3 were measured by Goldstein et al., [96] in the temperature range between 16 and 300K, and Justice and Westrum [92] in the temperature range between 5 and 350K. Goldstein et al., reported S_{298}° $154.47\text{J/mol}\cdot\text{K}$ [96] was estimated using from the experimental data and possible magnetic contribution. Justice and Westrum measured the low C_p data and observed the Schottky anomaly peak at about 10K. In addition, the spectroscopic data from the literature was reviewed and compared by Justice and Westrum to their own experimental electronic energy level data. Justice and Westrum reported the final result S_{298}° of $158.45\text{J/mol}\cdot\text{K}$ taking into account the additional $2R\ln 2$ for presumed thermal anomaly and lattice

contribution below 5K. In the present study, the experimental results of Justice et al., were re – evaluated to obtain S_{298}° of $\text{Nd}_2\text{O}_3 = 158.78\text{J/mol}\cdot\text{K}$.

4.3 Standard Entropy of Middle RE_2O_3

4.3.1 The S_{298}° of B and C – Sm_2O_3

The only low temperature heat capacities of B – Sm_2O_3 were measured by Justice and Westrum [91] in the temperature range between 5 and 350K. The electronic heat capacities could not be resolved quantitatively because of absence of knowledge on lattice contribution of B form of RE_2O_3 [91]. The experimental data by Justice and Westrum clearly showed the presence of a Schottky anomaly effect, however, the position of the C_p peak was ambiguous to determine especially because lattice contribution could not be separated. Using the same method as other RE_2O_3 which had thermal anomalies, Justice and Westrum calculated the S_{298}° of B – Sm_2O_3 to be $151.04\text{J/mol}\cdot\text{K}$.

The experimental low temperature C_p experimental data for C – Sm_2O_3 were absence in literature. Lyutsareva [17] estimated the S_{298}° of C – Sm_2O_3 using spectral data of Sm^{3+} ion in cubic Y_2O_3 crystals for the electronic contribution and C_p of both C – Eu_2O_3 for the lattice components. The estimated S_{298}° of C – Sm_2O_3 was $155.80 \pm 3\text{J/mol}\cdot\text{K}$.

In this work, the experimental data of Justice and Westrum [91] for B – Sm_2O_3 were used for the recalculation based on the same methodology introduced in the previous discussion of other RE_2O_3 . A slightly lower value of S_{298}° for B – Sm_2O_3 ($150.38\text{J/mol}\cdot\text{K}$) than the result by Justice and Westrum was obtained. For the C – Sm_2O_3 , the estimation by Lyutsareva et al., [17] estimation was not used. Instead, the trend of $\Delta S_{tr,C \rightarrow B}^{\circ}$ (section 6.2.1) was used to estimate S_{298}° of C – Sm_2O_3 . According to this trend, B form is predicted to have higher S_{298}° than C form. However, the estimation by Lyutsareva et al., told that S_{298}° of B – Sm_2O_3 is lower than that of C – Sm_2O_3 . The optimized S_{298}° of C – Sm_2O_3 in the study is $145.94\text{J/mol}\cdot\text{K}$.

4.3.2 The S_{298}° of B and C – Eu_2O_3

The low temperature heat capacity experimental data for both B and C – Eu_2O_3 were measured by Lyutsareva et al., [17] in the temperature range between 8 and 300K. Since the paramagnetic property of Eu_2O_3 is deficient as shown in the insert in Figure 12, both B and C form of Eu_2O_3 show the absence of the Schottky anomaly. In this work, the experimental data Lyutsareva et al., were used to recalculate the S_{298}° . Exactly the same values of 141.45J/mol·K and 142.74J/mol·K as the result of Lyustareva et al., were obtained for C and B – Eu_2O_3 in this work. However, it was both agreed in this study and Zinkevich [2] that the difference between the two S_{298}° should be larger in order to accommodate the thermodynamic consistency for C – B phase transition (T_{tr} , ΔH_{tr}° , ΔS_{tr}°). Consequently, minor modifications were made to yield the final results of S_{298}° to be 138.95J/mol·K and 144.25J/mol·K for C and B forms respectively.

4.3.3 The S_{298}° B and C – Gd_2O_3

The low temperature C_p data of C – Gd_2O_3 were measured by Justice and Westrum [91] in the temperature range between 7 and 350K. The entire range of thermal anomalies were not observed because of experimental limitations, therefore, by applying the spectral data, the positions of theoretical cooperative and Schottky anomalies were determined to be at 1.3K and 3.8K, respectively [91]. The final S_{298}° calculated by Justice and Westrum was 150.62J/mol·K, which was exactly the same to our recalculation.

The C_p data of B – Gd_2O_3 are unavailable in the literature. Lyutsareva et al., [17] used the similar method as their estimation for C – Sm_2O_3 to obtain the result of C – Gd_2O_3 . The estimated S_{298}° was 156.10J/mol·K. In the present study, the result of Justice and Westrum [91] for C – Gd_2O_3 and ΔS_{tr}° of C → B phase change (section 6.2.1) were used. That is, the optimized S_{298}° of B and C – Gd_2O_3 are 150.62J/mol·K and 155.50J/mol·K respectively in this study.

4.4 Standard Entropy of Heavy RE_2O_3

4.4.1 The S_{298}° of C – Dy₂O₃

The low temperature heat capacities of C type Dy₂O₃ were measured by Justice and Westrum [93] in the temperature range 6 to 350K. No other thermal anomaly was discovered experimentally except the double degeneracy at ground state, which contributed $2R\ln 2$ to the final S_{298}° [93]. Using the same method as Justice and Westrum used, 149.48J/mol·K is obtained in this study, which is in excellent agreement with the original S_{298}° 149.79J/mol·K by them.

4.4.2 The S_{298}° of C – Ho₂O₃

Justice and Westrum [93] measured the low temperature heat capacities for C – Ho₂O₃ from 6 to 350K. They further distinguished the thermal anomalies of Schottky and cooperative effects. As Justice and Westrum did, S_{298}° including ground state degeneracy ($2R\ln 3$) is calculated in this study to be 158.14J/mol·K, which is consistent with the value 158.16 J/mol·K by Justice and Westrum.

4.4.3 The S_{298}° of C – Er₂O₃

The low temperature C_p of C type Er₂O₃ were reported by Justice and Westrum [93] in the temperature range between 5 and 350K. The thermal anomaly peak at 35K was not obviously shown until the lattice contribution was removed from the main heat capacity data. It was proposed by Justice and Westrum that the presence of a probable cooperative anomaly below 10K might cause the hindering of the ground state degeneracy. As the result, the final S_{298}° 153.13J/mol·K of C – Er₂O₃ was calculated by them by adding $2R\ln 2$ as the effect of ground state degeneracy to the entropy calculation. Using the same method, we calculated S_{298}° to be 153.50J/mol·K was obtained in this study.

4.4.4 The S_{298}° of C – Tm₂O₃

The low temperature C_p data for C type of Tm_2O_3 were measured by Justice et al., [94] in the temperature range between 6 and 350K. The lattice contribution was calculated with the same methodology as other cubic RE_2O_3 in the study by Justice and his colleagues, but scaled accordingly because of Lanthanide contraction effect. Justice et al., assumed the ground state degeneracy contribution was singlets, which was excellently supported by magnetic susceptibility data provided by Brown and Hubbard [102] based on the experiments at 1.3 – 4.2K. Consequently, Justice et al., calculated the final S_{298}° to be 139.75J/mol·K. In this work, almost the same result 139.74J/mol·K is recalculated.

4.4.5 The S_{298}° of C – Yb_2O_3

The low temperature C_p data of C – Yb_2O_3 were measured by Justice and Westrum [91] in the temperature range between 5 and 350K. However, even at the lowest temperature point, the peak of the thermal anomaly was still not reached. Justice and Westrum stated that the trace of the thermal anomaly indicated the possible antiferromagnetic ordering at 2.5K [103], which could also be treated as the degeneracy at the ground state. As for the calculation of S_{298}° , Justice and Westrum also took into account for the degeneracy at the ground state $2R\ln 2$. The recalculated S_{298}° from this study is 133.77J/mol·K, which is very close to the original value by Justice and Westrum at 133.05J/mol·K.

4.4.6 The S_{298}° of C – Lu_2O_3

The low temperature C_p of C – Lu_2O_3 was measured by Justice et al., [94] in the temperature range between 6 and 350K. Compare to other RE_2O_3 , the effect of thermal anomaly is absent due to filled f – orbital of Lu_2O_3 . Therefore, the calculation of the S_{298}° is much simpler than other RE_2O_3 . By summing the integration of the available low temperature C_p data and extrapolation from 6K to 0K using the Debye method, 109.96J/mol·K is obtained for S_{298}° of C – Lu_2O_3 by Justice et al., and 109.91J/mol·K in this study.

4.5 Estimation of Missing S_{298}° for Pm_2O_3 and Tb_2O_3

The low temperature C_p of Pm_2O_3 and Tb_2O_3 were not available in the literature. In the study of Zinkevich [2], the estimated S_{298}° of Pm_2O_3 and Tb_2O_3 were 155.60J/mol·K and 156.91J/mol·K, respectively.

All the available experimental S_{298}° and calculated/optimized S_{298}° in this study are plotted in Figure 12. The paramagnetic moment (insert of Figure 14) and assessed standard entropies in Figure 12 show similar trend with atomic number. From the change of S_{298}° of cubic RE_2O_3 , S_{298}° of C – Pm_2O_3 is estimated to be 152.95J/mol·K (average of the values of C – Sm_2O_3 and C – Eu_2O_3).

In the case of C – Tb_2O_3 , simple linear average of the value of adjacent RE_2O_3 is less reasonable because of the mismatch between high paramagnetic moment (Figure 12) and low S_{298}° of neighbouring Dy_2O_3 . Fortunately, Hill [95] measured the low temperature magnetic (“electronic” according to the study by Justice et al., [90-94]) heat capacities below 22K and estimated the magnetic entropy from 0 to 22K. Using the available data from Hill, the contribution of magnetic S_{mag} to S_{298}° was calculated in this study. Then, S_{mag} at 298K was added to the lattice contribution of C – RE_2O_3 calculated using the method by Justice et al., to obtain the final S_{298}° to be 157.57J/mol·K.

5. Heat Capacity of RE_2O_3

All the available heat capacity data RE_2O_3 are plotted in Figure 13 to Figure 31. Even though, RE_2O_3 have multiple polymorph modifications, the available heat capacity data only covered the most stable phases for the light (A phase) and heavy (C phase) RE_2O_3 . For the middle RE_2O_3 , C_p data for both C and B phases were available. All the high temperature C_p data were calculated from original heat content data. In the figures, low temperature C_p data which were mainly obtained from adiabatic calorimetry are also plotted to examine the consistency of C_p data.

Pankratz et al., [101, 104-108], as one of the main contributors for C_p measurement, measured the heat content values of the entire RE_2O_3 except La_2O_3 and Pm_2O_3 . The second important research group was Tsagreishvili et al., [109-113] who measured heat content data of RE_2O_3 series ($\text{RE} = \text{Sc}, \text{Eu}, \text{Dy}, \text{Ho}, \text{Tm}$ and Yb). Shpil'rain et al., [32] performed heat content measurements covering phase transition of $\text{C} \rightarrow \text{H} \rightarrow \text{L}$ of Y_2O_3 . Experimental data were not available for radioactive Pm_2O_3 . The heat capacity function for Pm_2O_3 was estimated by taking the average of the C_p function coefficients of Nd_2O_3 and Sm_2O_3 .

For each RE_2O_3 , when more than one set of experimental data are available, the most reliable set or combined data sets from several authors were carefully assessed and used to generate the best heat capacity functions using computer-assisted regression program. The typical C_p function coefficients were used in this work is:

$$C_p = a + bT + cT^{-2} + dT^2$$

In the optimization of C_p function for $T > 298\text{K}$, the C_p data starting from 200K or less were used to get the smooth continuous functions from low temperature C_p . The optimized coefficients of all C_p functions of all the RE_2O_3 are listed in Table 18. In Figure 13 to Figure 31, the results of Zinkevich [2] are also plotted in dashed lines for comparison. The details of C_p evaluation for each RE_2O_3 are below.

5.1.1 Heat capacity of $\text{C} - \text{Y}_2\text{O}_3$

Extensive data [18, 32, 108, 114-117] were found for $\text{C} - \text{Y}_2\text{O}_3$ as shown in Figure 13. Low temperature data are from Goldstein et al., [96].

Curtis [117] reported a series of properties of Y_2O_3 , including heat content from 473K to 1473K. Pankratz et al., [108] and Landa et al., [114] measured heat content using drop calorimetry from 298 to 1799K and from 1300 to 2100K respectively. The heat content values from Yashvili et al., [116], who used 99.94% purity Y_2O_3 ranged from 389K to 1615K. Seminko et al., [115] investigated $H_T - H_{298}$ from 1194K to 2468K. The heat content values from Shpil'rain et al., [32]

ranged from 1883K to 2919K, which covered three phases, C, H and L. Kolitsch [18] investigated the heat capacity using stepwise heating and continuous heating in the temperature range between 650 and 1650K. As shown in Figure 13, experimental data from Curtis were already scattering below 800K, while the result by Pankratz et al., and Yashvili et al., overlapped with great consistency. Above 1200K, data of Pankratz et al., started to show scattering and reached maximum variation at around 1400K. Although Seminko et al., and Shpil'rain et al., studied heat content above 2000K, their data scattering was too severe to obtain a reasonable C_p function. In this work, the data from Landa et al., Kolitsch, Yashvili et al., and Pankratz et al. below 1200K were used to construct the heat capacity function. As can be seen in Figure 13, the C_p curve from Zinkevich [2] deviates gradually from the present C_p function with increasing temperature.

5.1.2 Heat Capacity of C – Sc₂O₃

The experimental heat content data were measured by Pankratz and Kelley [104] and Tsagareishvili et al., [110] at 298 – 1800K and 298 – 1600K, respectively. Shpil'rain et al., [21] was the only researcher who reported enthalpy measurements up to 2930K including liquid phase. Leonidov et al., [40] has studied various properties related to Sc₂O₃ including heat capacities in his thesis. As presented in Figure 14, the optimized C_p data from Leonidov showed great agreement with the results of Pankratz and Kelley, and Tsagareishvili et al., and also exhibited smooth connection with low temperature C_p data from Weller and King [98]. Data from Shpil'rain et al., were overly scattered as usual. In this work, the optimized data by Leonidov et al., were employed to calculate the C_p function. The C_p optimized by Zinkevich [2] was somewhat lower than the result from this work. Zinkevich might have used the scattered data from Pankratz and Kelley above 1400K (Figure 14).

5.2 Heat Capacity of Light RE₂O₃

5.2.1 The Heat Capacity of A – La₂O₃

Heat content data of La₂O₃ were reported by Blomeke and Ziegler [118] and King et al., [99] at 383 – 1172K and 30 – 2000K, respectively. As seen in Figure 15, the data by King et al.,

showed great consistency with the low temperature C_p data from Justice and Westrum [92], Goldstein et al., [96], and also the result of Blomeke and Ziegler for high temperature C_p . Therefore, the results of King et al., Blomeke and Ziegler were used together to produce the C_p function in this work. The results from Zinkevich [2] agreed excellently with this work.

5.2.2 The Heat Capacity of A – Ce₂O₃

The heat capacity experimental data above room temperature were obtained by Pankratz and Kelley [105], Kuznetsov and Rezhukhina [119] at 398 – 1500K and 578 – 1116K, respectively. Low temperature C_p data were measured by Weller and King [98], Justice and Westrum [90] and Huntelaar et al., [53]. A few extrapolation data points for high temperature C_p were also reported by Huntelaar et al. The results of Kuznetsov and Rezhukhina were systematically lower than the extrapolation from low temperature C_p data. Even though, Pankratz and Kelley reported considerable number of experimental data, the quality was too poor to fix a C_p function. The poor accuracy of the results of Pankratz and Kelley might result from the starting non – stoichiometric material (Ce₂O_{3.3}) instead of the stoichiometric compound Ce₂O₃. The α – β transition reported by Pankratz and Kelley were neither discussed clearly in their own study nor supported by any other literature. α was measured as Hexagonal structure, while β was not characterized by Pankratz and Kelley. Therefore, the results by Pankratz and Kelley, Kuznetsov and Rezhukhina were excluded from the optimization of C_p function. In this work, the data extrapolated by Huntelaar et al., up to about 800K were used to optimize the C_p function of A – Ce₂O₃. The C_p data calculated from Zinkevich [2] are slightly higher than the present line (Figure 16).

5.2.3 The Heat Capacity of A – Pr₂O₃

Heat content data for Pr₂O₃ were reported by Pankratz [101] in the range between 400 and 1600K, and the low temperature C_p data were limited to the personal communication between Gruber and Lutsareva [100]. As discussed previously (section 4.2.3) on standard entropy, the experimental data from Lutsareva were quantitatively adjusted by Gruber to align the high temperature C_p from Pankratz. In this work, whole range of the data by Pankratz were used to calculate the C_p function.

5.2.4 The Heat Capacity of A – Nd₂O₃

High temperature heat content data for Nd₂O₃ were measured by Blomeke and Ziegler [118] at 383 – 1172K and Pankratz et al., [108] at 400 – 1800K. Data reported by both authors showed consistency with the low temperature C_p data measured by Goldstein et al., [96] and Justice and Westrum [92]. However, some scattering were observed in the data by Pankratz above 1300K as shown in Figure 18. Therefore, all available data below 1300K by Blomeke and Ziegler, and Pnakratz et al., were used to produce the C_p function of A – Nd₂O₃. As presented in the figure, the C_p line produced by Zinkevich [2] was reasonable until 1300K shows the deviation from the present optimized C_p function.

5.3 Heat Capacity of Middle RE₂O₃

5.3.1 The Heat Capacity of C and B – Sm₂O₃

Sm₂O₃ is stable in either C or B form at room temperature, therefore, heat content data for the two polymorphs were measured. Pankratz and Kelley [106] reported data for C and B structures 405 – 1150K and 403 – 1798K, respectively. Gvelesiani et al., [120] reported data for C – Sm₂O₃ at 394 – 1147K and B – Sm₂O₃ at 396 – 1617K. Both studies on C – Sm₂O₃ were discontinued around 1150K because C→B phase transition occurs at 1153K (section 2.1). The C_p function of C – Sm₂O₃ was optimized using data from both Pankratz and Kelley, and Gvelesiani et al. As shown in Figure 19, the C_p line produced by Zinkevich [2] started to deviate from this work after 1150K.

In the study of Pankratz and Kelley [106] on B – Sm₂O₃, a thermal anomaly was observed near 1195K as shown in Figure 20. Since the cause of this anomaly was neither discussed by Pankratz nor reported in the study Gvelesiani et al., [120], the anomaly was excluded in the evaluation of C_p . The C_p function was optimized using the whole ranges of data from both studies. It should be noted that both data sets are consistent with the data from Justice and Westrum [91]. The optimized C_p in this work shows negligible difference comparing to C_p optimized by Zinkevich [2].

5.3.2 The Heat Capacity of C and B – Eu₂O₃

Experimental heat content data on C – Eu₂O₃ were reported by Pankratz and Kelley [106], Tsagareishvili and Gvelesiani [109], Gilchrist and Preston [121] in the temperature ranges at 400 – 1350K, 400 – 1200K and 298 – 973K respectively as shown in Figure 21. These C_p data are consistent with low temperature C_p data from Lyutsareva [17]. Due to the phase transition of C→B at 1348K, heat content data of C – Eu₂O₃ were not available above this temperature. The C_p function was optimized by employing all the data [106, 109, 121]. The C_p established by Zinkevich [2] was slightly higher than the C_p from this work.

The heat content data on B – Eu₂O₃ were obtained by researchers Pankratz and Kelley [106], Gvelesiani et al., [120] and Gilchrist and Preston [121] at 400 – 1800K, 383 – 1589K, and 298 – 973K, respectively. The results of Gvelesiani et al., are consistent with other results until 1200K. Then, a significant scattering is shown. It should be also noted that all C_p results are consistent with low temperature C_p from Lyutsareva [17], as can be seen in Figure 22. In this work, all C_p data except the part of data by Gvelesiani et al., were used to obtain the optimized C_p function of B – Eu₂O₃.

5.3.3 The Heat Capacity of C and B – Gd₂O₃

The heat contents of C – Gd₂O₃ were reported only by Pankratz and Kelley [106] in the temperature range at 400 – 1550K. The C_p derived from the heat content data are plotted in Figure 23 and they are consistent with the low temperature C_p data by Justice and Westrum [91]. The C_p of B – Gd₂O₃ were investigated by Pankratz and Kelley [106] and Shpil’rain et al., [122] in the temperature ranges at 400 – 1802K and 1600 – 2400K, respectively. The C_p function of C – Gd₂O₃ is optimized based on the data by Pankratz and Kelley.

For B – Gd₂O₃, the result of Shpil’rain et al., [122] were not employed in the present C_p optimization because of poor accuracy as shown in Figure 24. Therefore, the C_p function of B – Eu₂O₃ was calculated only using the results of Pankratz and Kelley [106]. For both C and B – Gd₂O₃, the present C_p functions are in an excellent agreement with the functions by Zinkevich [2].

5.4 Heat Capacity of Heavy RE₂O₃

5.4.1 The Heat Capacity of C – Tb₂O₃

Heat contents of C – Tb₂O₃ were investigated by Pankratz [101] at 400 – 1600K. Low temperature C_p data have not been measured. Therefore, the C_p function was determined only based on the results of Pankratz. The resultant C_p in this study is similar to that of Zinkevich [2] as shown in Figure 25.

5.4.2 The Heat Capacity of C – Dy₂O₃

High temperature heat content data for C – Dy₂O₃ were measured by Pankratz and Kelley [105] in the temperature range at 400 – 1800K. Tsagareishvili and Gvelesiani [113] also measured the heat contents in the temperature range between 400 and 1600K. The C_p derived from both studies are plotted in Figure 26. As can be seen both C_p are consistent with low temperature C_p by Justice and Westrum [91]. The scattering of the results by Pankratz and Kelley becomes significant above 1000K, which is originated from anomaly in heat content. This anomaly was not found by Tsagareishvili and Gvelesiani. Therefore, the C_p function was optimized using experimental C_p data below 1000K from both Pankratz and C_p data from Tsagareishvili and Gvelesiani. The C_p function in this study and Zinkevich [2] were in excellent agreement as seen in Figure 26.

5.4.3 The Heat Capacity of C – Ho₂O₃

Heat content data for Ho₂O₃ were measured by Pankratz and King [107], Tsagareishvili and Gvelesiani [112] in the temperature range from 400 to 1800K. The C_p values derived from both studies are consistent with the low temperature C_p data [93]. Therefore, available data above room temperature were all taken into account for the optimization of C_p function of C – Ho₂O₃, and the result is shown with all available experimental data in Figure 27.

5.4.4 The Heat Capacity of C – Er₂O₃

Heat contents of C – Er₂O₃ were measured by Pankratz and King [107] from 400K to 1800K. The C_p derived [107] is in consistent with low temperature C_p reported by Justice and Westrum [93]. The C_p data from Pankratz and King were used to obtain the C_p function. The experimental data and the C_p curve from this study are plotted in Figure 28.

5.4.5 The Heat Capacity of C – Tm₂O₃

High temperature heat content data of C – Tm₂O₃ were reported by Pankratz and King [107] from 400K to 1800K, Tsagareshvili and Gvelesiani [109] at 400 – 1600K. Similar to the results by Pankratz [105] for Dy₂O₃, a thermal anomaly was observed for Tm₂O₃ near 1680K. The similar explanation was given by Pankratz but we found not convincing. Therefore, data above 1600K were excluded from calculation for C_p function. It is observed in Figure 29 that C_p function by Zinkevich [2] showed excellent agreement with this study.

5.4.6 The Heat Capacity of C – Yb₂O₃

Heat content values for C – Yb₂O₃ were measured by Pankratz and King [107] in the temperature between 400 and 1800K, Tsagareishvili and Gvelesiani [109] at 400 – 1600K. Similar to Dy₂O₃ and Tm₂O₃, thermal anomaly was observed by Pankratz and King at 1365K with heat absorption of 628J/mol. As usual, the thermal anomaly was excluded from calculation of C_p function. The resultant C_p curve from this study and experimental data are plotted in Figure 30.

5.4.7 The Heat Capacity of C – Lu₂O₃

Heat capacities of the C – Lu₂O₃ above room temperature were derived from the heat content data by Pankratz and Kelley [105] in the temperature range between 400 and 1800K. As presented in Figure 31, the derived C_p data are consistent with the low temperature C_p reported by Justice et al., [94]. The C_p function from this study also strongly supported by Zinkevich [2] and can reproduce the experimental data by Pankratz and Kelley.

6. The Enthalpy and Entropy Changes of Phase Transitions

Rare earth sesquioxides have different polymorph stabilities under various temperature and pressure conditions. The T_{tr} of stable and metastable phase transformations at 1atm was introduced above (section 2.1 to 2.6). In this section, P_{tr} will be introduced as the other factor to induce phase transitions. Then, the enthalpy and entropy of phase transitions, ΔH_{tr}° and ΔS_{tr}° will be derived from available thermodynamic information.

The ΔH_{298}° , S_{298}° and C_p derived above can only construct Gibbs energy functions of the most stable phases which are stable at room temperature. The knowledge of ΔH_{tr}° and ΔS_{tr}° allow to extend to a completed thermodynamic database with 6 Gibbs energy functions for C, B, A, H, X and L phases of each RE_2O_3 . In this study, when the C_p of given polymorph RE_2O_3 is unavailable, its C_p was assumed to be the same to that of the nearest stable polymorph of each RE_2O_3

Equation 2

$$\Delta G_{tr}^\circ = \Delta H_{tr}^\circ - T \Delta S_{tr}^\circ$$

Equation 3

$$\Delta H_{tr}^\circ = (\Delta H_{298,j}^\circ - \Delta H_{298,i}^\circ) + \int_{298}^T C_{p,tr} dT$$

Equation 4

$$\Delta S_{tr}^\circ = (\Delta S_{298,j}^\circ - \Delta S_{298,i}^\circ) + \int_{298}^T C_{p,tr}/T dT$$

where “i” and “j” are two adjacent polymorphs of RE_2O_3 . At the phase transition temperature, T_{tr} , $\Delta G_{tr}^\circ = 0$.

Equation 5

$$\Delta H_{tr}^\circ = \Delta S_{tr}^\circ \times T_{tr}$$

If the T_{tr} is known, the ΔS_{tr}° can be calculated from ΔH_{tr}° or vice versa.

with the assumption of $\Delta C_{p,tr} = 0$,

Equation 6

$$\Delta H_{tr}^\circ = (\Delta H_{298,j}^\circ - \Delta H_{298,i}^\circ)$$

Equation 7

$$\Delta S_{tr}^{\circ} = (\Delta S_{298,j}^{\circ} - \Delta S_{298,i}^{\circ})$$

For example, if the ΔH_{298}° , S_{298}° and C_p of stable C phase at room temperature are known, the Gibbs energy of B phase can be calculated from T_{tr} , and ΔH_{tr}° and ΔS_{tr}° with assumed C_p or experimental determined C_p of B phase. The Gibbs energy functions of other phases stable at high temperature or metastable (A, H, X, L) can be built up step by step using the same approach. In each step, as the accuracy of ΔH_{tr}° and ΔS_{tr}° between transition phases determines the accuracy of Gibbs energy of polymorphs of RE_2O_3 , special attentions were given to find the most reliable ΔH_{tr}° and ΔS_{tr}° using systematic analysis of all RE_2O_3 simultaneously.

The ΔH_{tr}° and ΔS_{tr}° were usually not directly measured, so various approaches were applied depending on available data types. In general, in the present study the following approaches for C→B transition, Clausius – Clapeyron relationship were used. For B→A transition, DFT calculated data and limited heat content data were available. For A→H, H→X and X→L, the limiting slope rule and binary phase diagram was applied to determine ΔH_{tr}° . The details of the methodologies for each phase transition are explained below.

6.1 Methodologies for Determining ΔH_{tr}° and ΔS_{tr}°

6.1.1 The C→B Transition

Many ΔH_{298}° , S_{298}° and C_p are available for both B and or C forms of Sm_2O_3 , Gd_2O_3 and Eu_2O_3 , as discussed above (section 3.3 and 4.3). Then, by using the relationship In Equation 5, the unknown values can be calculated.

The Clausius – Clapeyron relationship allows to proceed by using pressure induced phase transition data to calculate ΔH_{tr}° and ΔS_{tr}° for other RE_2O_3 in light and heavy groups. Before applying this relationship, two assumptions must be set: (1) same C_p functions of every phase of RE_2O_3 , and (2) molar volume is independent of temperature or pressure. As mentioned above,

when no C_p data available for a given phase, it is assumed that the C_p of a given polymorph is the same as C_p of nearest stable polymorph at room temperature. In fact, when C_p of C and B polymorphs of Sm_2O_3 , Eu_2O_3 , and Gd_2O_3 , the difference in C_p depending on the crystal structure was not significant. So this assumption can be reasonable. Regarding the molar volume assumption, the thermal expansibility and compressibility data are very scarce, so this assumption can be still acceptable.

The Clausius – Clapeyron relationship between the most stable phase and the subsequent higher phase can be expressed as:

Equation 8

$$\frac{dP}{dT} = \frac{\Delta S}{\Delta V} = \frac{\Delta S_{298,tr}^\circ}{\Delta V_{298,tr}}$$

Once $\Delta S_{298,tr}^\circ$ is calculated from the experimental phase transition T – P relations, the ΔH_{tr}° can be calculated from the known T_{tr} at 1atm.

The transition pressure data for applying Clausius – Clapeyron relationship were not only measured using *in situ* experiments, but also calculated from DFT (Density Functional Theory). The available experimental and calculated data are summarized in Table 19.

6.1.2 The B→A Transition

The $\Delta H_{tr,B \rightarrow A}^\circ$ of the entire RE_2O_3 , excluding Eu_2O_3 and Yb_2O_3 , were obtained by Wu et al., [123] using DFT calculation. In their study, the energies of formation of both B and A were reported and the energy difference was assumed as the transition energy ΔH_{tr}° .

The continuous heat content data including the event of B→A transition for Gd_2O_3 were measured by Barkhatov et al., [20]. So ΔH_{tr}° of Gd_2O_3 can be obtained from their experiment and ΔS_{tr}° can be calculated from ΔH_{tr}° and T_{tr} . In addition, a few pressure induced phase transition data, including experimentally measured data and calculated data using *ab initio* method were reported

[124-129]. In this case, the Clausius – Clapeyron relationship was applied to obtain $\Delta H_{tr,B \rightarrow A}^\circ$ and $\Delta S_{tr,B \rightarrow A}^\circ$.

6.1.3 The A→H, H→X and X→L Transitions

The thermodynamic enthalpy and entropy data for A→H, H→X and melting are very limited. Barkhatov et al., [20] measured heat content data of Gd₂O₃ and reported an unexpectedly large ΔH_{tr}° for A→H transition (34.73 ± 3.35 KJ/mol), which is not accepted in this study. Therefore, the so – called limiting slope rule, which connects ΔH_{tr}° (or ΔS_{tr}°) to liquidus of binary phase diagram is used to derive ΔH_{tr}° and ΔS_{tr}° in this study. In the binary system,

Equation 9

$$\frac{dT}{dX_i} = \frac{2RT_{tr}}{\Delta S_{tr}^\circ}$$

where $\frac{dT}{dX_i}$ is the slope of liquidus, and T_{tr} and ΔS_{tr}° are the transition temperature and entropy, respectively. In order to apply such rule, the solid which form liquidus is ideally a stoichiometric phase. Among available binary RE₂O₃ oxide systems, a series of RE₂O₃ – Al₂O₃ systems show a stoichiometric RE₂O₃ phase. Therefore, RE₂O₃ – Al₂O₃ systems were used for this analysis. Fortunately, assessment of the RE₂O₃ – Al₂O₃ phase diagram by Wu and Pelton [28] is available. In fact, when Wu and Pelton performed their optimization of the binary systems, they used the same limiting slope rule to evaluate the ΔH_{tr}° and ΔS_{tr}° of A→H, H→X and X→L transitions.

For example, the optimized phase diagram of the Nd₂O₃ – Al₂O₃ systems [28] is presented in Figure 32 along with experimental data [26]. As can be seen in “circle 1”, the liquidus slope near melting temperature can give the ΔS_{tr}° of X – Nd₂O₃. The same analysis was performed for all binary RE₂O₃ – Al₂O₃ systems. The slope of liquidus of Nd₂O₃ at the A – H and H – X transitions (circled area 2 and 3 in Figure 32) shows negligible changes. This observation is a strong indication for the small entropy differences between A and H, and H and X. The similar observations were found for all the RE₂O₃ – Al₂O₃ binary systems [28]. This finding allowed to

apply the same value $\Delta S_{tr} = 2.5 \text{ J/mol.K}$ on both $A \rightarrow H$ and $H \rightarrow X$ transitions of the entire RE_2O_3 family.

The entropies of fusion of entire RE_2O_3 family (except Sc_2O_3), regardless of solid polymorph for melting, their diverse last solid phases, were extracted from Wu and Pelton [28], Roth [130] for the $\text{RE}_2\text{O}_3 - \text{Al}_2\text{O}_3$ phase diagrams using the limiting slope rule. The ΔS_{fus}° of Sc_2O_3 with magnitudes 100.42 KJ/mol and 127 KJ/mol were reported by Shpil'rain et al., [21] and Leonidov et al., [40] respectively.

For Lu_2O_3 , ΔS_{fus}° extracted from Wu and Pelton's [28] $\text{Lu}_2\text{O}_3 - \text{Al}_2\text{O}_3$ phase diagram also represent $\Delta S_{tr,C \rightarrow L}^\circ$. The complexity was significantly increased because more energy terms were involved, namely: (1) transition energies of $C \rightarrow B$ and $B \rightarrow A$, (2) $\Delta S_{tr,A \rightarrow H}^\circ, \Delta S_{tr,H \rightarrow X}^\circ, T_{tr,C \rightarrow L}$ and (3) $\Delta H_{tr,H \rightarrow X}^\circ$ to calculated properties of $A \rightarrow H$ and $X \rightarrow L$. During calculation, it was found either of the two unknowns $T_{tr,X \rightarrow L}$ or $T_{tr,A \rightarrow H}$ must be determined in order to obtain $\Delta H_{tr,X \rightarrow L}^\circ$ and $\Delta H_{tr,A \rightarrow H}^\circ$. In this study, $T_{tr,X \rightarrow L}$ was fixed first because of relatively fair consistency of adjacent sesquioxides in comparison with data of $T_{tr,A \rightarrow H}$ as shown in Figure 4 and Figure 6. The similar situation also occurred for Sc_2O_3 that $\Delta H_{tr,A \rightarrow H}^\circ$ and $\Delta H_{tr,H \rightarrow X}^\circ$ were calculated by taking average of the corresponding values of the rest of the RE_2O_3 . Examples for detailed determination of discrete energy terms were illustrated in detail in section 6.2.3.

6.1.4 The Shock Induced $C \rightarrow A$ Phase Transition

Shock induced phase change $C \rightarrow A$ was observed for Sc_2O_3 and Sm_2O_3 [129, 131, 132]. In addition, the same type $C \rightarrow A$ transition was also reported for Gd_2O_3 and Y_2O_3 [131]. This transition is not stable transition, or reversible [131]. So these transition data were not taken into account in the present study.

6.2 The Optimized Results of ΔH_{tr} and ΔS_{tr}

6.2.1 The ΔH_{tr}° and ΔS_{tr}° of $C \rightarrow B$ Phase Transition

The ΔH_{tr}° and ΔS_{tr}° of C→B phase transition obtained in this study are plotted using in Figure 33 and Figure 34, and listed in Table 20. In general, ΔH_{tr}° and ΔS_{tr}° are decreasing and increasing linearly with ionic radii, respectively.

The experimental ΔH_{298}° [16, 47, 68, 71] and S_{298}° data [17, 91] for the three middle rare earth sesquioxides Sm_2O_3 , Eu_2O_3 and Gd_2O_3 are available. Large uncertainties were found in the ΔH_{298}° for Eu_2O_3 [16, 71]. The ΔH_{tr}° value at 298K for Eu_2O_3 calculated from Lyutsareva's experimental entropies [17] did not locate along the general linear trend as shown in Figure 33 . The ΔH_{298}° values for Sm_2O_3 and Gd_2O_3 calculated using the estimated entropies by Lyutsareva et al., and experimental entropies by Justice and Westrum [91] aligned perfectly with the general linear trend as shown in Figure 33. The ΔH_{tr}° and ΔS_{tr}° for the three middle RE_2O_3 were selected accordingly with the best set of standard ΔH_{298}° and S_{298}° (section 3.3).

The data of pressure induced C→B phase transition obtained from various authors [19, 128, 133-136] using both experimental techniques and DFT method were estimated in this study to apply the Clausius – Clapeyron relationship. Among all the pressure data, the results of Hoekstra [19] were the most widely accepted in literature because of the broad range of his work from Sm_2O_3 to Er_2O_3 at three different temperatures. As shown in Figure 33 and Figure 34, values calculated from Hoekstra were also supported by the values obtained from the experimental ΔH_{298}° and S_{298}° [16, 17, 47, 68, 71, 91], especially for Sm_2O_3 and Gd_2O_3 . Therefore, the result of Hoekstra were generally accepted in this study.

According to experimental T_{tr} data (section 2.1), stable C→B transformation does not occur at 1 atm in the lanthanide oxide series before Pm_2O_3 (La_2O_3 – Nd_2O_3) and after Ho_2O_3 (Y_2O_3 – Lu_2O_3). The unavailability of the study by Hoekstra [19] was observed starting from Tm_2O_3 as seen in Figure 33 and Figure 34. For heavy RE_2O_3 after Tm_2O_3 and two rare earth like oxides Y_2O_3 and Sc_2O_3 , a linear extrapolation based on the results calculated from the phase transition P – T relation by Hoekstra was used to obtain hypothetical ΔH_{tr}° and ΔS_{tr}° . For light RE_2O_3 before Pm_2O_3 , the same linear relationship was used to estimate ΔH_{tr}° and ΔS_{tr}° . But found the B – Nd_2O_3 was more stable than A – Nd_2O_3 at room temperature. Therefore, the ΔH_{tr}° of Nd_2O_3 was slightly modified to 1.38KJ/mol, which was slightly lower than the original value calculated from the linear

trend established from the results of Hoekstra. Using the adjusted ΔH_{tr}° for Nd_2O_3 and carefully selected ΔH_{tr}° for $\text{Sm}_2\text{O}_3 - \text{Gd}_2\text{O}_3$, a separate linear trend was established to describe enthalpy of C→B phase change in the range $\text{La}_2\text{O}_3 - \text{Gd}_2\text{O}_3$. In this way, the stable A phase for light RE_2O_3 can be still calculated at room temperature. It should be noted that the estimated ΔH_{tr}° is negative for La_2O_3 , Ce_2O_3 and Pr_2O_3 . The discontinuity in the linear trend for ΔH_{tr}° was also found at Gd_2O_3 in the assessment of Zinkevich [2]. For optimized ΔS_{tr}° of RE_2O_3 the values varied from 5 J/mol·K to 4 J/mol·K when RE_2O_3 is varied from La_2O_3 to Lu_2O_3 .

Although the present optimized ΔH_{tr}° and ΔS_{tr}° for C→B transition results are similar to those of Zinkevich [2], one of the fundamental difference is in the T_{tr} . Some of the C→B transition temperatures used by Zinkevich were very different from the experimental temperatures [7, 13-15, 18] especially for the middle RE_2O_3 as shown in Figure 10. Therefore, the present optimization is more accurate than the work by Zinkevich. In addition, the ΔH_{tr}° , ΔS_{tr}° and T_{tr} for La_2O_3 to Nd_2O_3 were not optimized by Zinkevich.

6.2.2 The ΔH_{tr}° and ΔS_{tr}° of B→A Phase Transition

The ΔH_{tr}° and ΔS_{tr}° of B→A phase transition data were plotted in Figure 35 and Figure 36, and listed in Table 21. Although not all RE_2O_3 have stable B→A transition, the ΔH_{tr}° data for the entire RE_2O_3 family, except Eu_2O_3 and Yb_2O_3 , were calculated by Wu et al., [123] using DFT. The available ΔH_{tr}° and ΔS_{tr}° data show decreasing trends with increasing of ionic radii.

Prior to the study by Wu et al., [123], thermodynamic data of B→A transition were only available for Sm_2O_3 , Eu_2O_3 and Gd_2O_3 from P – T transition experiments [124-129]. Similar to the previous C→B transition, Clausius – Clapeyron relationship was employed to obtain ΔS_{tr}° , which were applied together with assessed $T_{tr,B\rightarrow A}$ (see Figure 3). The only calorimetric ΔH_{tr}° was obtained by Barkhatov et al., [20] for heat content data of Gd_2O_3 . As shown in Figure 35, the ΔH_{tr}° from DFT calculations by Wu et al., [123] is reliable because the ΔH_{tr}° from their work show good agreement with not only the calorimetric ΔH_{tr}° [20] but also the ΔH_{tr}° derived from P – T transition data [124-129]. The ΔH_{tr}° for the two exceptions Eu_2O_3 and Yb_2O_3 can be estimated from the trend

of the available results from Wu et al. The estimated ΔH_{tr}° for Eu_2O_3 overlaps with the experimental data from Chen et al., [125] and Guo et al., [128] as shown in Figure 35. The DFT data of Wu et al. and the estimated data of Eu_2O_3 and Yb_2O_3 are accepted in this study for ΔH_{tr}° of B→A transition.

Regarding the entropy of transition, the data presented in Figure 36 can be divided into three parts. The first part is from Pm_2O_3 to Dy_2O_3 , where stable B→A transition occurs and the assessed T_{tr} is available (see Figure 3). ΔS_{tr}° for these RE_2O_3 were calculated from ΔH_{tr}° and T_{tr} . The second part includes $\text{Ho}_2\text{O}_3 - \text{Lu}_2\text{O}_3$, Y_2O_3 and Sc_2O_3 . ΔS_{tr}° of these RE_2O_3 were calculated from ΔH_{tr}° estimated T_{tr} of metastable B→A transition. The third part is light RE_2O_3 . Wu et al. calculated negative ΔH_{tr}° values and T_{tr} is not properly estimated. If the general trend of ΔS_{tr}° for the first and second parts are followed, negative ΔS_{tr}° can be predicted for light RE_2O_3 . However, negative ΔS_{tr}° seems to be less probable, because the entropy is highly dependent on the structure of RE_2O_3 . So A phase higher entropy than B phase, regardless of RE_2O_3 . If ΔS_{tr}° is two positive, A phase can be more stable than B phase at room temperature. Therefore, ΔS_{tr}° of light RE_2O_3 were all assigned to be 0.05J/mol·K in this study.

Large disagreement on ΔS_{tr}° was observed between results optimized in this study and Zinkevich [2]. The difference becomes large between Pm_2O_3 to La_2O_3 . For Pm_2O_3 , the reason of large difference between Zinkevich and the present study is due to T_{tr} . Zinevich used $T_{tr} = 936\text{K}$ for Pm_2O_3 , while the present study accepts the $T_{tr} = 2013\text{K}$ from experimental study [12]. Therefore, the optimized ΔS_{tr}° of Pm_2O_3 in this study should be more reliable than that of Zinkevich. Most probably, the ΔS_{tr}° of B→A transition of La_2O_3 to Nd_2O_3 by Zinkevich would be over-estimated.

6.2.3 The ΔH_{tr}° and ΔS_{tr}° of A→H, H→X and X→L Transitions

As discussed in section 6.1.3, ΔS_{tr}° of A→H and H→X were set to be 2.5J/mol·K in this study. Then, from ΔS_{tr}° and T_{tr} , ΔH_{tr}° can be calculated as shown in Table 22. The fusion entropies $\Delta S_{tr,X \rightarrow L}^\circ$ for $\text{La}_2\text{O}_3 - \text{Dy}_2\text{O}_3$, $\Delta S_{tr,H \rightarrow L}^\circ$ for $\text{Ho}_2\text{O}_3 - \text{Yb}_2\text{O}_3$, $\Delta S_{tr,C \rightarrow L}^\circ$ for Lu_2O_3 extracted from Wu

and Pelton [123], and $\Delta S_{tr,H \rightarrow L}^\circ$ for Y_2O_3 extracted from Roth [130] and $\Delta S_{tr,C \rightarrow L}^\circ$ for Sc_2O_3 extracted from Shpil'rain et al., [21] were listed in Table 22. If all these ΔH_{tr}° and ΔS_{tr}° of $A \rightarrow H$, $H \rightarrow X$, and $X \rightarrow L$ are combined with ΔH_{tr}° and ΔS_{tr}° of $C \rightarrow B$ and $B \rightarrow A$, and ΔH_{298}° and ΔS_{298}° of the most stable phase at room temperature, ΔH_{298}° and ΔS_{298}° of all phases can be determined as listed in Table 23. Although the standard transition sequence of RE_2O_3 is $C \rightarrow B \rightarrow A \rightarrow H \rightarrow X \rightarrow L$. Four types of combined transitions were observed: $B \rightarrow H$, $C \rightarrow H$, $H \rightarrow L$ and $C \rightarrow L$. The ΔH_{tr}° and ΔS_{tr}° of these combined transitions can be calculated using the Hess's law using data from Table 23.

The calculated $\Delta H_{tr,A \rightarrow H}^\circ$, $\Delta H_{tr,B \rightarrow H}^\circ$ and $\Delta H_{tr,C \rightarrow H}^\circ$ are plotted in Figure 37 and compare with the results of Zinkevich [2] and limited experimental data from Barkhatov et al., [20] and Shpil'rain et al., [32]. The estimated $\Delta H_{tr,C \rightarrow H}^\circ$ for Y_2O_3 in this study shows excellent agreement with the experimental data reported by Shpil'rain et al., as seen in Figure 37. The $\Delta H_{tr,A \rightarrow H}^\circ$ reported by Zinkevich are significantly higher than the results from this study. The estimation by Zinkevich on $\Delta H_{tr,A \rightarrow H}^\circ$ was entirely based on the study of Barkhatov et al., on Gd_2O_3 , which is proved not reliable from the discussion of liquidus slope in 6.1.3.

Up till this stage, all the available information for constructing the thermodynamic database of the entire RE_2O_3 were completed. All the assessed and estimated standard enthalpies and entropies were shown in Table 23. The C_p functions were previously discussed in section. In total, 102 Gibbs energy functions for 17 RE_2O_3 with 6 different phases were produced. The thermodynamic database was then applied to produce binary $RE_2O_3 - RE_2O_3$ phase diagrams for validation purposes.

7. Main Differences between the Study of Zinkevich and This Work

As shown in each section, most of the results accepted in this study were compared with the results from Zinkevich [2]. Some of the main differences were observed in T_{tr} of $C \rightarrow B$ and

B→A, and ΔH_{tr}° and ΔS_{tr}° of B→A, A→H and meltings, which caused large differences of ΔH_{tr}° and ΔS_{tr}° in B→H C→H, and H→X transitions.

7.1 Transition Temperature

For the temperature of C→B transition as shown in *Table 1*, the results of this study, which were obtained from critical review of available experimental data (section 2.1), were much higher than the results from Zinkevich [2], which were extracted from optimized $Y_2O_3 - RE_2O_3$ (RE = Sm, Eu and Gd) phase diagrams. In his phase diagrams, the limited binary phase diagram data of C + B phase are not sufficient to support low T_{tr} of C→B. The magnitude of $T_{tr, C\rightarrow B}$ of Pm_2O_3 from the study of Zinkevich, which is almost half of the experimental value, is obtained entirely from linear extrapolation without any experimental proof.

For the temperature of B→A transition as shown in *Table 1*, the result of Zinkevich [2] for Pm_2O_3 936K is less than half in magnitude compare to experimental result 2013K accepted in this study. The low temperature from Zinkevich might due to the assumed parabolic trend of ΔS_{tr}° used for prediction of Pm_2O_3 . The ΔS_{tr}° predicted by Zinkevich was probably used subsequently to calculate $T_{tr, B\rightarrow A}$.

Table 1 Main differences of transition temperatures between the study of Zinkevich [2] and this work

Sesquioxides	T, K	T, K
	Zinkevich	This work
<i>C→B</i>		
Pm_2O_3	457	973
Sm_2O_3	676	1153
Eu_2O_3	894.5	1348
Gd_2O_3	1425	1561
<i>B→A</i>		
Pm_2O_3	936	2013

7.2 The Enthalpy and Entropy of Transitions

The ΔH_{tr}° of B \rightarrow A transition from Zinkevich [2] do not have unacceptably large differences with the values selected in this study from the DFT calculated results of Wu et al., [123] as seen in Table 2. It should be noted that B \rightarrow A transition is metastable that the negative value of ΔH_{tr}° or the small empirical $\Delta S_{tr}^\circ=0.05\text{J/mol.K}$ used in this study does not give influential effect on future thermodynamic calculations. The positive values of ΔS_{tr}° in the study of Zinkevich are the results of prediction using a parabolic trend as mentioned in previous section 7.1.

One of the main disagreement between this work and the study of Zinkevich [2] is the ΔH_{tr}° and ΔS_{tr}° of A \rightarrow H transition as seen in Table 2. It is found that the ΔH_{tr}° value from Barkhatov used by Zinkevich gives exceptionally large ΔS_{tr}° , which causes A phase is overly stable. The assumed $\Delta S_{tr}^\circ=2.5\text{J/mol.K}$ of this study is used because of our observation from well – established $\text{Al}_2\text{O}_3 - \text{RE}_2\text{O}_3$ phase diagrams mainly from the study of Wu and Pelton [28]. Subsequently, using the critically assessed T_{tr} , ΔH_{tr}° of A \rightarrow H is calculated. Because of the questionable data used by Zinkevich for A \rightarrow H transition, the results of the combined transitions B \rightarrow H and C \rightarrow H are less reasonable. For examples in Table 2, the same $\Delta S_{tr}^\circ=13.99\text{J/mol.K}$ is used for both A \rightarrow H and B \rightarrow H transitions ; ΔS_{tr}° of A \rightarrow H and B \rightarrow H transitions is larger than C \rightarrow H transition, which is supposed to include more polymorphic configurations C \rightarrow B \rightarrow A \rightarrow H.

The experimental ΔH_{tr}° and ΔS_{tr}° of meltings (X \rightarrow L, H \rightarrow L, C \rightarrow L) are unavailable except for Sc_2O_3 and Y_2O_3 , therefore, all the values must be properly estimated. The methodologies used by Zinkevich [2] and this study are very different that results show large disagreements as seen in Table 2. In the study of Zinkevich, an empirical equation involving factors of volume change, Grüneisen parameter and heat capacity was used. In this study, the limiting slope rule was applied on optimized $\text{Al}_2\text{O}_3 - \text{RE}_2\text{O}_3$ phase diagrams, which have strongly supported experimental data near pure RE_2O_3 sides. Subsequently, the properties of H \rightarrow X were calculated with known properties of meltings and properties of other discrete transitions. The disagreements in meltings also cause the differences in H \rightarrow X transition between both studies.

Table 2 Main differences of the enthalpy and entropy of transitions between the study of Zinkevich [2] and this work

8. Thermodynamic Modeling of Binary R'₂O₃ – R''₂O₃

In this study, the Gibbs energy of all stable and metastable C, B, A, H, X and L phases of 17 RE₂O₃ including Sc₂O₃ and Y₂O₃ were optimized. Based on these Gibbs energies, the binary R'₂O₃ – R''₂O₃ systems were optimized in this study. There is no thermodynamic properties data in the binary systems. The only available data are phase diagrams. So all the available phase diagrams were reproduced using the regular solution model. As these RE₂O₃ shows the systematic changes in physical – chemical properties, we believe that there would be a trend in the regular solution parameters in the binary RE₂O₃ systems. In the present study, liquid phase was assumed as an ideal solution. The regular solution model applied to solid solutions can be expressed as:

Equation 10

$$g_{soln} = X_{RE'2O3} g_{RE'2O3}^{\circ} + X_{RE''2O3} g_{RE''2O3}^{\circ} + 2RT(X_{RE'2O3} \ln X_{RE'2O3} + X_{RE''2O3} \ln X_{RE''2O3}) + \omega X_{RE'2O3} X_{RE''2O3}$$

where $g_{RE'2O_3}^\circ$, and $g_{RE''2O_3}^\circ$ are the Gibbs energy functions for pure RE_2O_3 component in either stable or metastable forms, $X_{RE'2O_3}$ and $X_{RE''2O_3}$ are mole fractions of RE_2O_3 component, ω is a regular solution parameter. In the entropy of mixing term, 2 moles of energy of mixing per one mole of solution was considered because of $(RE^{3+}, RE^{3+})_2O_3$ solution has two mole of sites for mixing per mole of formula. It should be noted that Zinkevich [2] did the similar optimization of the binary RE_2O_3 systems. But he used the “1” mole of entropy of mixing per mole of formula, which is less accurate.

The calculated binary phase diagrams were presented from Figure 38 to Figure 48. Adylov et al., [137] investigated the phase diagrams of $Y_2O_3 - Nd_2O_3$. Shevthenko et al., [138] measured the phase diagrams of $Y_2O_3 - Sm_2O_3$, and Gd_2O_3 . The phase diagram of $Y_2O_3 - Eu_2O_3$ was measured by Andrievskaya and Lopato [139] in their study of ternary systems $ZrO_2 - Y_2O_3 - Eu_2O_3$. $Y_2O_3 - Dy_2O_3$ binary phase diagram was measured by Nigmanov and Shevthenko [140]. In their studies [137-140], phases above 2000K were measured using DTA technique. Samples with phases lower than 2000K were obtained by annealing and the compositions were characterized using X – ray analysis. A series of binary phase diagrams consist of La_2O_3 with other RE_2O_3 ($RE = Nd, Sm, Gd, Dy, Ho, Er$) were investigated by Coutures and Foex [10] using thermal analysis.

Some disagreements were observed between calculated phase diagrams and experimental data in the $Y_2O_3 - Sm_2O_3$, $Y_2O_3 - Eu_2O_3$ and $Y_2O_3 - Nd_2O_3$ systems. In the binary $Y_2O_3 - Nd_2O_3$ phase diagram as shown in Figure 38, the boundary of “C + B” two phase region overlapped with the two experimental data [137] marked with cross. The boundary of “B + A” two phase region did not match with experimental data points reported by Adylov et al., [137]. In the $Y_2O_3 - Sm_2O_3$ and $Y_2O_3 - Eu_2O_3$ binary systems as shown in Figure 39 and Figure 40, some mismatches were observed between calculated two phase boundaries and experimental data [138, 139]. It should be noted that regular solution model is an extremely simple model. More accurate Y_2O_3 related binary phase diagrams can be produced using a more sophisticated solution model.

On the contrary of the Y_2O_3 related binary phase diagrams, excellent matches between the calculated La_2O_3 related phase diagrams and experimental data [10] were observed from Figure

43 to Figure 48. Most of the experimental data from Coutures and Foex [10] described the phase boundaries of H and X phases, only a few data were available for A phase as shown in Figure 45 to Figure 47. Therefore, the reliability of the calculated phase boundaries for C and B phases was probably ambiguous. It is observed that the stability of A phase decreases in the binary system of the $\text{La}_2\text{O}_3 - \text{Nd}_2\text{O}_3$ to $\text{La}_2\text{O}_3 - \text{Er}_2\text{O}_3$, and B phase appears with strong stability in the $\text{La}_2\text{O}_3 - \text{Sm}_2\text{O}_3$ system. B phase is eventually replaced by C phase in the $\text{La}_2\text{O}_3 - \text{Er}_2\text{O}_3$ system.

The optimized regular solution parameters are listed in Table 3. All parameters are positive, which tells the repulsive interactions between RE' and RE'' . In general, with the closer the ionic radii between the two RE_2O_3 components, the smaller the parameters are needed for C, B and A phases. The parameters of H and X phases show opposite trend. For example, Dy_2O_3 is closer to Y_2O_3 compare to Nd_2O_3 , the parameters used in C, B and A phases appears to be smaller in the $\text{Y}_2\text{O}_3 - \text{Dy}_2\text{O}_3$ interaction than the $\text{Y}_2\text{O}_3 - \text{Nd}_2\text{O}_3$ interaction. For H and X phases, the parameters of $\text{Y}_2\text{O}_3 - \text{Dy}_2\text{O}_3$ system are larger than those of $\text{Y}_2\text{O}_3 - \text{Nd}_2\text{O}_3$ system. This trend found may not be used to roughly predict the phase diagram of the binary $\text{R}'_2\text{O}_3 - \text{R}''_2\text{O}_3$ systems.

In comparison with the phase diagrams and solution parameters reported by Zinkevich [2], it is found that the accuracies of the phase diagrams are comparable, however the parameters used in this work are much smaller. The large differences are observed especially in A and H phases. The reason for this is unreliably large experimental ΔH_{tr} of $\text{A} \rightarrow \text{H}$ transition was accepted by Zinkevich (see Figure 37). Therefore, large parameters were necessary to bring down the stability of H phase in the binary RE_2O_3 systems.

9. Conclusion

All the available thermodynamic data and phase transition data of RE_2O_3 have been critically and systematically evaluated in this study to obtain the best set of 102 Gibbs energy functions of 17 RE_2O_3 including Sc_2O_3 and Y_2O_3 . For all stable and metastable C, B, A, H, X and L phases, ΔH_{298}° , S_{298}° , C_p , and phase transition temperature are prepared.

- The temperature of each discrete and combined transitions were reviewed and the best set of values were selected based on rigorous assessment of all the available data in the

literature. The transition temperatures of metastable phase transformations were also predicted according to the thermodynamic enthalpy and entropy of transition data.

- For the standard enthalpies of formation, the experimental techniques and reaction schemes were critically reviewed and compared. The best set of data for ΔH_{298}° was obtained based on experimental accuracy and systematic changes along with atomic number of RE. From the systematic trend, ΔH_{298}° of Pm_2O_3 which has not been available in the literature was reasonably predicted.
- The standard entropies of RE_2O_3 were examined by recalculation using the available experimental low temperature heat capacity data. During the calculation process, the concepts of lattice and magnetic contributions were considered. The unavailable S_{298}° of Tb_2O_3 and Pm_2O_3 were estimated properly either using the properties of adjacent RE oxides or the predicted lattice and magnetic C_p .
- The C_p data above room temperature were carefully assessed. C_p functions were produced by fitting the selected experimental data into the general C_p function form and plotted up to 3000 K. For the middle RE_2O_3 , two C_p functions were produced because of their dual stabilities of C and B phases at room temperature. The C_p functions of B phase of the middle RE_2O_3 were adopted for higher temperature phases A, H, X and L because unavailability of the data. However, for the rest of RE_2O_3 , C_p function was available for the phase stable at room temperature (C in heavy RE_2O_3 and A for light RE_2O_3). This function was adopted for all other stable and metastable phases (C, B, A, H, X, L).
- For C→B transition, the ΔH_{tr}° and ΔS_{tr}° were obtained from various data sources, including: assessed standard energies of the middle RE_2O_3 , pressure – temperature phase transition data, and *ab initio* calculations. All the results obtained using various methodologies were discussed that a linear trend was established between ΔH_{tr} and ionic radii (and also ΔS_{tr} vs. ionic radii) to estimate the ΔH_{tr}° and ΔS_{tr}° for the C→B transition of the entire RE_2O_3 .
- For B→A transition, the ΔH_{tr} data from *ab initio* calculations were mostly employed in this study because of its great reliability and consistency. The ΔS_{tr}° values were mostly determined by considering the assessed T_{tr} . However, the ΔS_{tr}° for the light RE_2O_3 were slightly modified to ensure stability of A phase at room temperature.
- For A→H and H→X transitions, a very small ΔS_{tr}° was estimated in this work because of the observations of small RE_2O_3 liquidus slope changes in the $\text{RE}_2\text{O}_3 - \text{Al}_2\text{O}_3$ phase

diagrams where such transition occurs in literature. For $X-L\Delta S_{fus}^{\circ}$ were calculated from $RE_2O_3 - Al_2O_3$ phase diagrams by applying the limiting slope rule. The ΔH_{tr} values were mostly determined by considering the assessed T_{tr} , while some ΔH_{tr} were determined by considering temperature and energies of combined transitions $B \rightarrow H$, $C \rightarrow H$, $H \rightarrow L$ and $C \rightarrow L$.

The optimized Gibbs energy functions were tested for the thermodynamic modeling of the binary $RE'_2O_3 - RE''_2O_3$ systems. In the modeling, a simple regular solution model was applied for all solid solutions and liquid was assumed as ideal solution. It was found that much smaller regular solution parameters were required to reproduce the available phase diagram data compared to the previous thermodynamic assessment.

The Gibbs energy database of RE_2O_3 constructed in this work can be readily used for the building of new thermodynamic database for binary, ternary and multicomponent systems containing RE_2O_3 .

10. Appendix

Figure 1 An example of binary RE_2O_3 phase diagram by Coutures and Foex [10]: binary La_2O_3 – Ho_2O_3 system; red circles indicate the extrapolated T_{tr} .

Figure 2 Summary of C→B phase transition temperatures depending on RE ionic radii; ASS: assessment; EST: estimation; DTA: differential thermal analysis; QM: quenching method; XRD: X – ray diffraction; TA: thermal analysis; UNK: method unknown; ionic radii in unit Å.

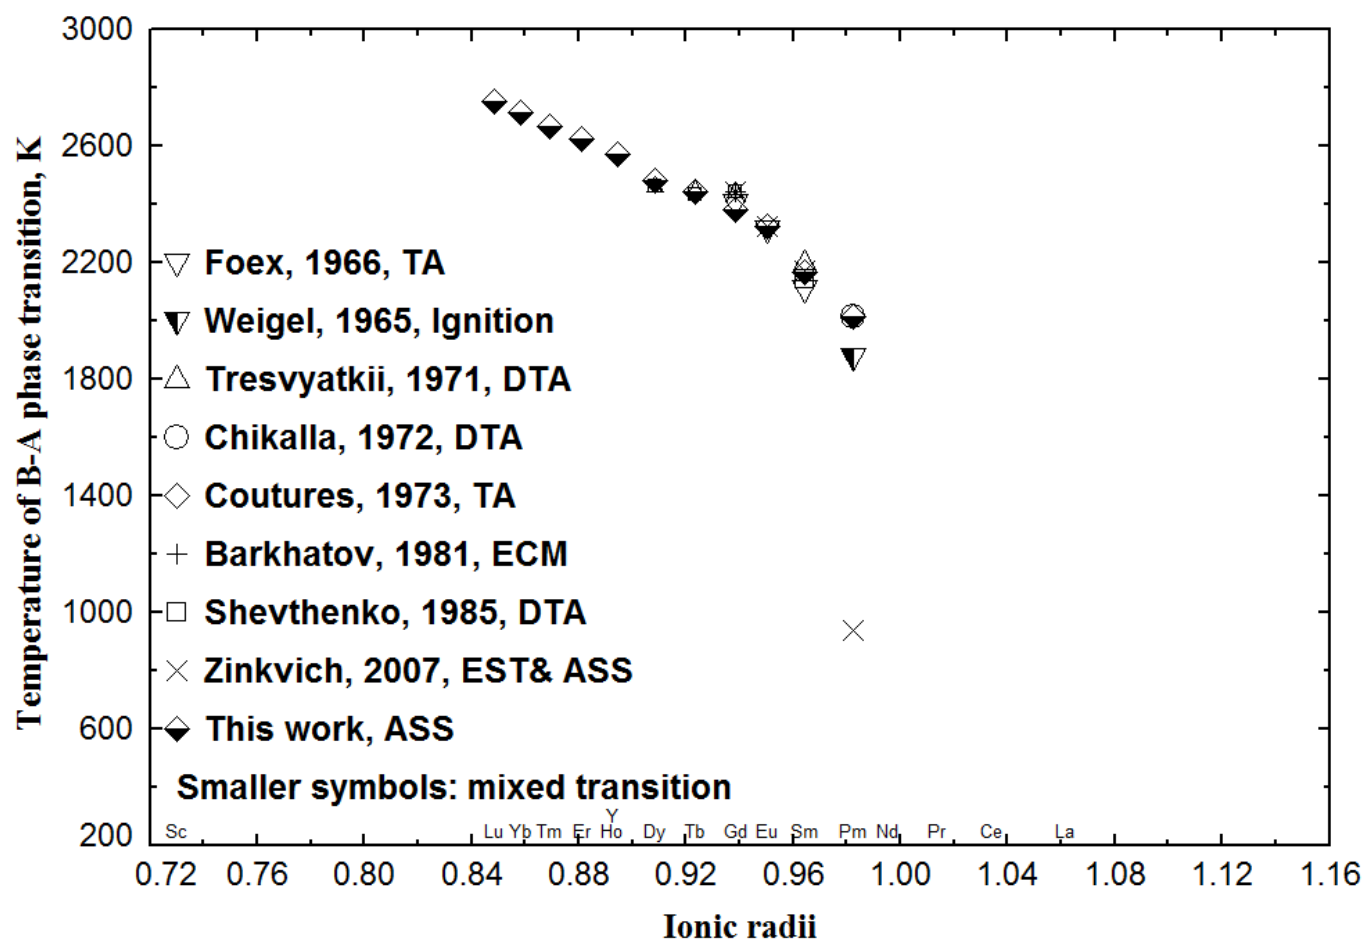

Figure 3 Summary of B→A phase transition temperatures depending on RE ionic radii; ASS: assessment; EST: estimation; ECM: electric conductivity measurement; DTA: differential thermal analysis; QM: quenching method; XRD: X – ray diffraction; TA: thermal analysis; ionic radii in unit Å.

Figure 4 Summary of A→H phase transition temperatures depending on RE ionic radii; ASS: assessment; EST: estimation; DTA: differential thermal analysis; XRD: X – ray diffraction; TA: thermal analysis; ionic radii in unit Å.

Figure 5 Summary of H→X phase transition temperatures depending on RE ionic radii; ASS: assessment; EST: estimation; DTA: differential thermal analysis; XRD: X – ray diffraction; TA: thermal analysis; ionic radii in unit Å.

Figure 6 Summary of X→L phase transition temperatures depending on RE ionic radii; ASS: assessment; EST: estimation; DTA: differential thermal analysis; XRD: X – ray diffraction; TA: thermal analysis; ionic radii in unit Å.

Figure 7 Summary of C→H phase transition temperatures depending on RE ionic radii; ASS: assessment; ECM: electric conductivity measurement; EST: estimation; DTA: differential thermal analysis; XRD: X – ray diffraction; TA: thermal analysis; ionic radii in unit Å.

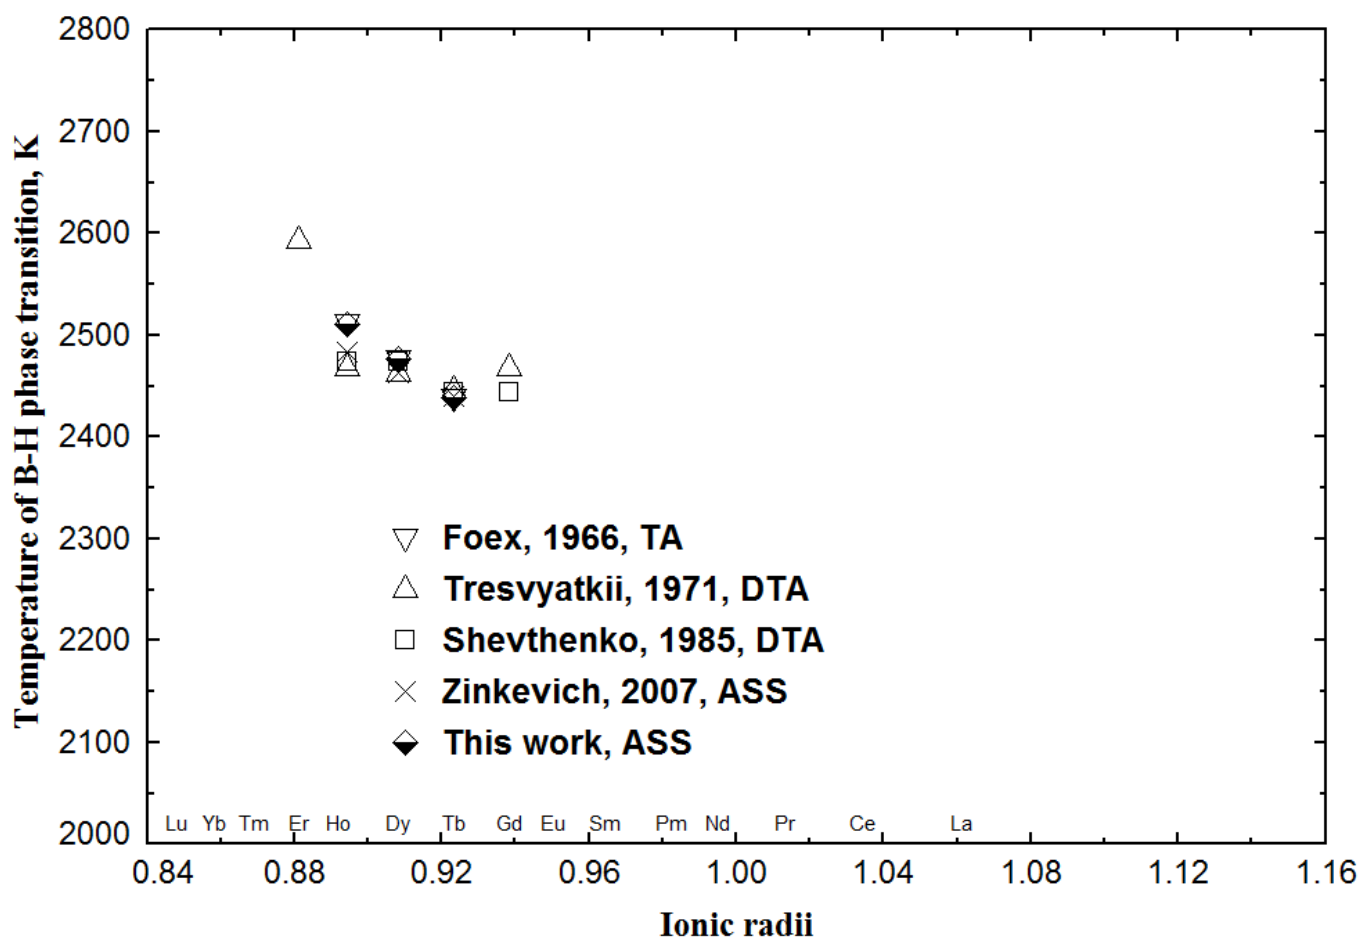

Figure 8 Summary of B→H phase transition temperatures depending on RE ionic radii; ASS: assessment; DTA: differential thermal analysis; XRD: X – ray diffraction; TA: thermal analysis; ionic radii in unit Å.

Figure 9 Summary of H→L phase transition temperatures depending on RE ionic radii; ASS: assessment; ECM: electric conductivity measurement; EST: estimation; DC: drop calorimetry; DTA: differential thermal analysis; XRD: X – ray diffraction; TA: thermal analysis; ionic radii in unit Å.

Figure 10 The optimized phase transition diagram of entire RE_2O_3 in this study; C: cubic; B: monoclinic; A: hexagonal; H: high temperature hexagonal; X: high temperature cubic; L: liquid; ionic radii in unit Å.

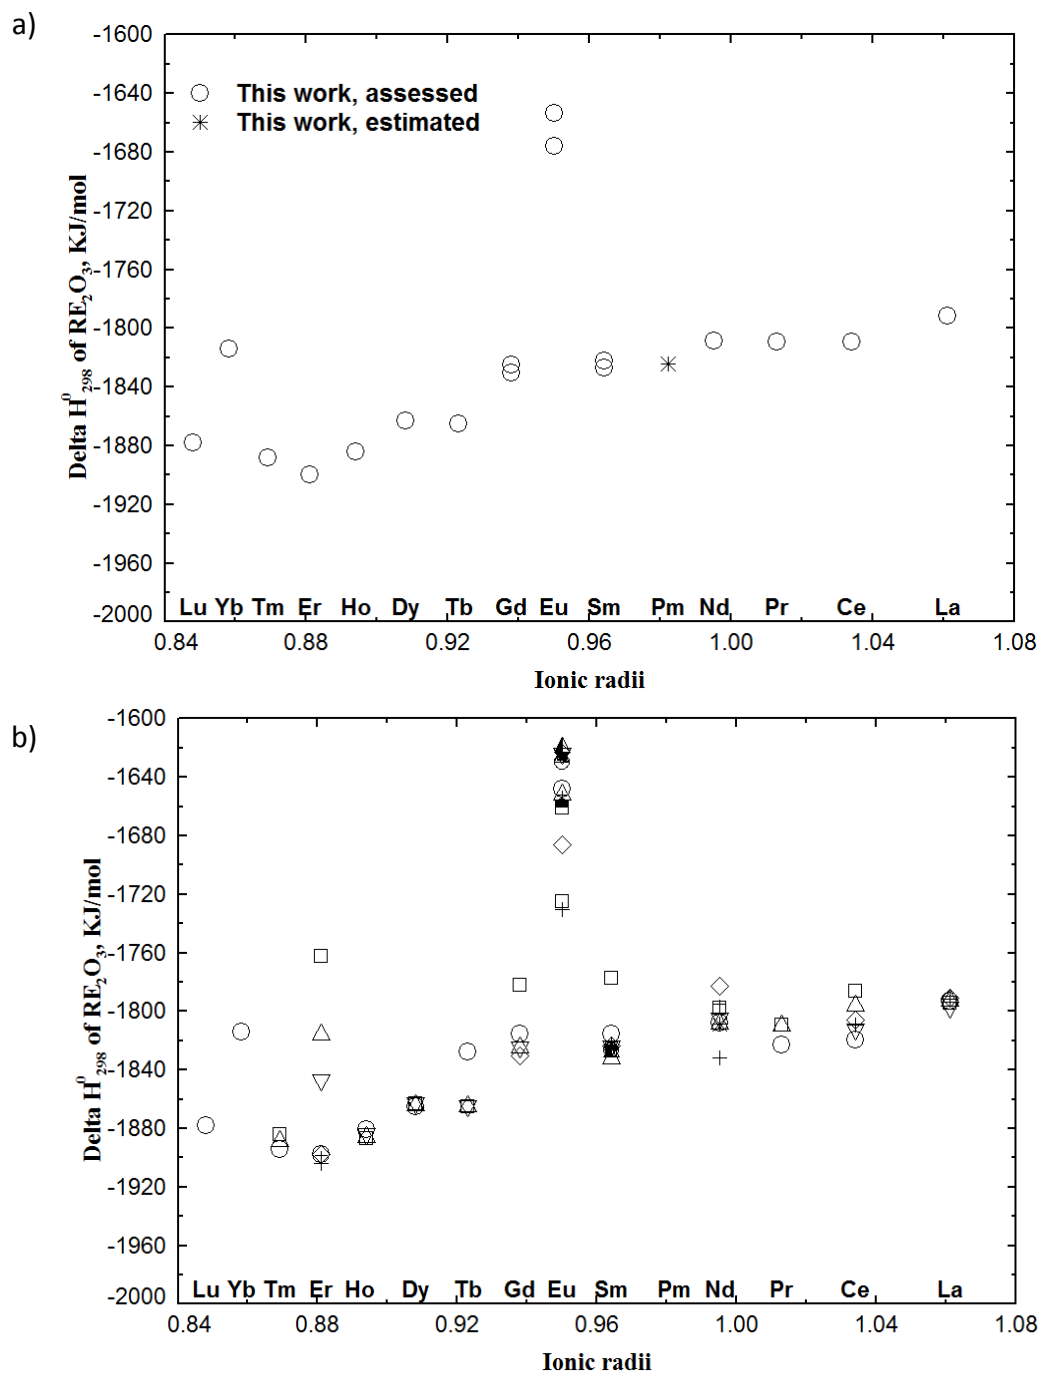

Figure 11 Standard enthalpy of formation of RE_2O_3 . (a) Optimized ΔH°_{298} in this study and (b) experimental ΔH°_{298} in the literature; ionic radii in unit Å. References of (b) are listed in Table 16.

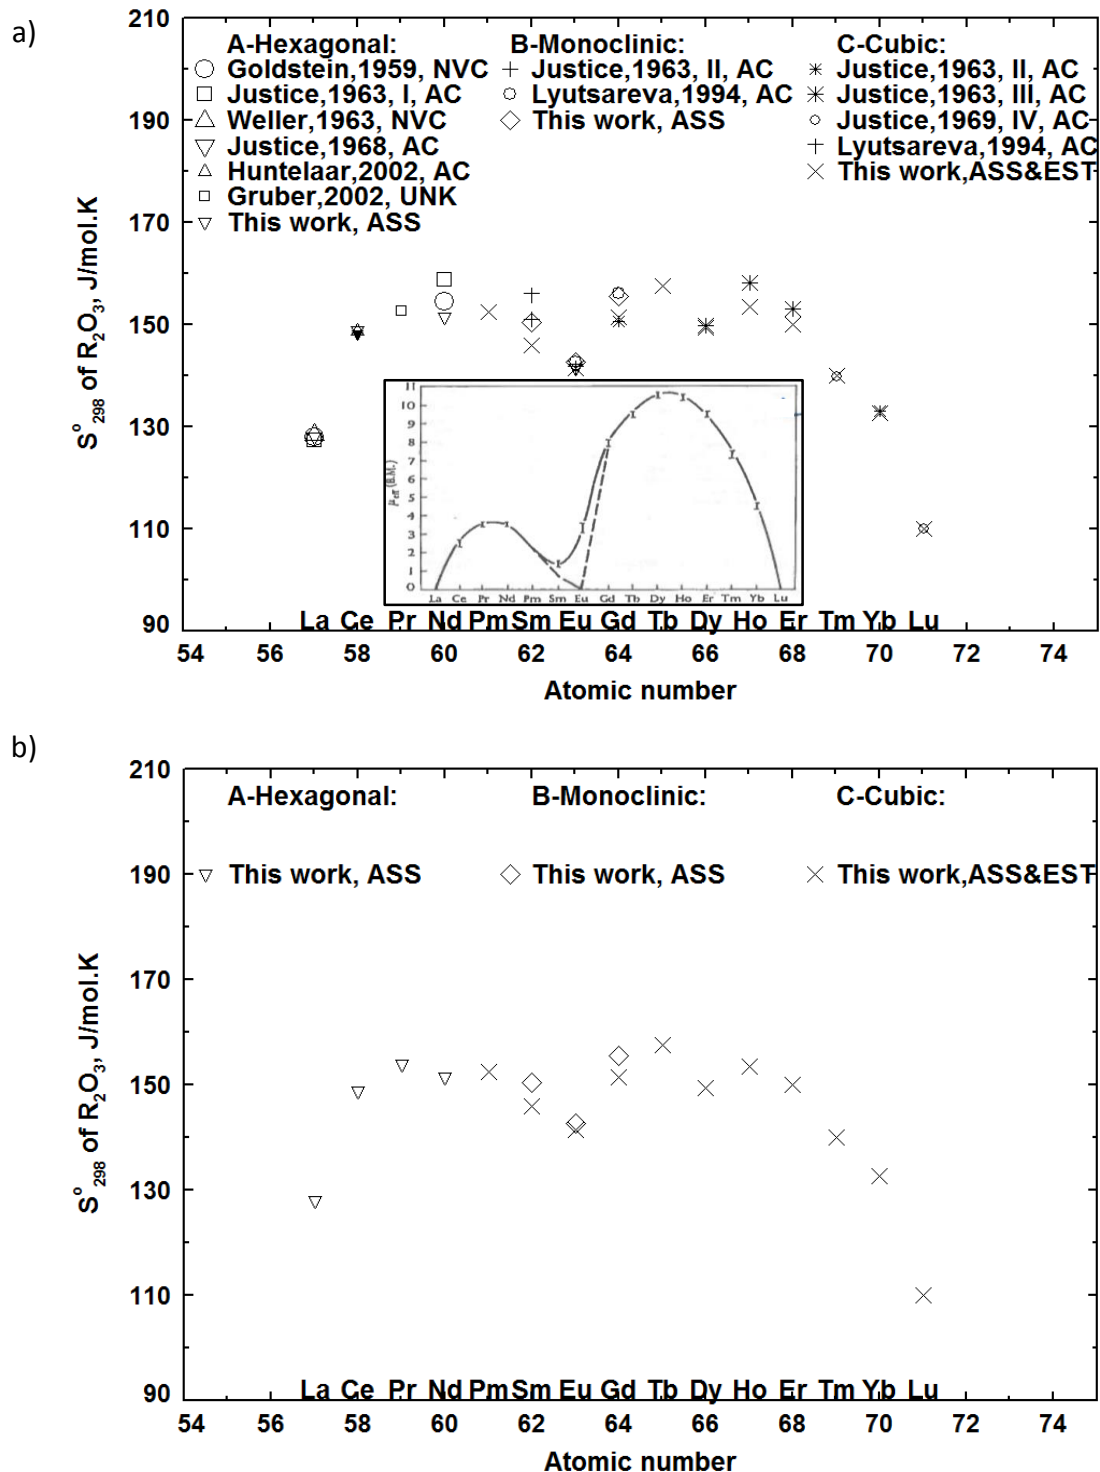

Figure 12 The standard entropies of Lanthanide sesquioxides;(a) experimental results; (b) optimized results; AC: adiabatic calorimetry; ASS: assessed; EST: estimation; NVC Nernst vacuum calorimetry; the small figure in the middle indicated the effective paramagnetic moment of RE^{3+} [145], dotted line: at 0K; solid line: at room temperature.
