Abstract

Chronic pain is one of the leading causes of disability and reduced quality of life worldwide. As a result of chronic pain, the prefrontal cortex (PFC) undergoes significant structural and functional remodeling, resulting in the loss of grey matter, altered synapse formation, and changes in neurotransmitter and ion channel signalling. These changes are accompanied by widespread alterations in gene expression and can be reversed if pain is attenuated by therapeutic intervention. The combination of widespread changes in gene expression with a reversible phenotype implicates epigenetics as a potential regulatory mechanism underlying chronic pain development and maintenance. Previous research has demonstrated the involvement of DNA methylation, an epigenetic mechanism, in mediating chronic pain. However, its response across the chronic pain time course and to interventions is poorly understood. Increased understanding of PFC DNA methylation in response to chronic pain and therapeutic interventions will reveal mechanisms of chronic pain development and identify possible novel therapeutic targets.

This thesis hypothesized that the PFC undergoes dynamic changes in DNA methylation as chronic pain develops over time, and that pharmacological and non-pharmacological interventions would counteract or prevent pain-related changes in methylation. These hypotheses were investigated through three research aims:

1) Track and observe PFC DNA methylation in response to induced neuropathic pain for up to 12 months post-injury

2) After chronic pain has developed, determine the PFC DNA methylation response to a pharmacological intervention of s-adenosylmethionine (SAM)

3) After chronic pain has developed, determine the PFC DNA methylation response to a non-pharmacological intervention of voluntary exercise

We found that spared nerve injury (SNI) resulted in rapid and persistent changes in DNA methylation, with robust differential methylation observed at one day post-injury and up to 12 months post-injury. We identified hundreds of differentially methylated genes, including those with known functions in pain, affecting domains related to stimulus response at early time points, immune function at later time points and actin and cytoskeletal regulation throughout the time course (Manuscript I). This study confirmed the involvement of PFC DNA methylation throughout the chronic pain time course, and identified time point specific changes in DNA methylation across pain-related genes and domains.

To explore the response of DNA methylation to intervention, SAM and voluntary exercise were provided after SNI in two separate experiments. Chronic administration of SAM beginning 3 months after injury resulted in attenuation of neuropathic pain and differential methylation of over 4000 genomic regions. These regions were related to functional domains of intracellular signaling, cell locomotion and migration, cytoskeletal structure, and cell adhesion (Manuscript II). Providing access to voluntary exercise after injury also resulted in the attenuation of neuropathic pain and the differential methylation of over 5000 genomic regions. These regions were related to functional domains of ion transport and homeostasis, cell adhesion and locomotion, and immune functioning and morphogenesis (Manuscript III). In each experiment, providing therapeutic intervention resulted in the reversal of pain-related DNA methylation changes in over 1000 genomic

regions. These studies confirmed the responsiveness of PFC DNA methylation to intervention after chronic pain, and that therapeutic intervention reverses the methylation status of a subset of chronic pain affected genes.

The work presented in this thesis demonstrates that PFC DNA methylation is dynamic and responsive to the development of chronic pain and therapeutic intervention. These results increase the understanding of how chronic pain is regulated in the PFC during its development and treatment, and which functional domains are predominantly affected by DNA methylation. This thesis provides the foundation for future investigations to explore how epigenetic mechanisms mediate chronic pain development and for future therapies to target epigenetic mechanisms to alleviate chronic pain.

Résumé

La douleur chronique est l'une des causes principales de perte d'autonomie et de réduction de la qualité de vie dans le monde. En réponse à la douleur persistante, le cortex préfrontal (CPF) subit d'importants remodelages structuraux et fonctionnels, conduisant à une perte de matière grise, une altération de la formation des synapses et des changements dans la signalisation des neurotransmetteurs et des canaux ioniques. Ces changements s'accompagnent d'une altération généralisée de l'expression des gènes et peuvent être contrecarrés si la douleur est soulagée par une intervention thérapeutique. La combinaison de changements généralisés dans l'expression des gènes avec un phénotype réversible suggère que l'épigénétique est un mécanisme de régulation potentiel qui sous-tend le développement et le maintien de la douleur chronique. Des recherches antérieures ont démontré l'implication de la méthylation de l'ADN, un mécanisme épigénétique, dans la médiation de la douleur chronique, mais sa réponse au travers de l'évolution de la douleur chronique et aux interventions est mal comprise. Une meilleure compréhension de la méthylation de l'ADN du CPF en réponse à la douleur chronique et aux interventions thérapeutiques permettra de révéler les mécanismes sous-jacents du développement de la douleur chronique et contribueront à l'identification de nouvelles cibles thérapeutiques possibles.

Cette thèse repose sur l'hypothèse que le CPF subit des changements dynamiques dans méthylation de l'ADN au fur et à mesure que la douleur chronique se développe, et que des interventions pharmacologiques et non pharmacologiques

corrigeraient ou empêcheraient ces changements. Cette hypothèse a été explorée à travers trois objectifs de recherche:

1) Décrire et suivre sur 12 mois la méthylation de l'ADN du CPF en réponse à une douleur neuropathique induite.
2) Après le développement de la douleur chronique, déterminer la réponse de la méthylation de l'ADN dans le CPF suite à une intervention pharmacologique utilisant la s-adénosylméthionine (SAM).
3) Après le développement de la douleur chronique, déterminer la réponse de la méthylation de l'ADN dans le CPF en réponse à une intervention non pharmacologique basée sur l'exercice volontaire.

Nous avons constaté que la lésion partielle du nerf sciatique, ou SNI, entraînait des changements rapides et persistants de la méthylation de l'ADN au niveau du CPF, avec une puissante méthylation différentielle observée dès le premier jour et qui persistait jusqu'à 12 mois. Nous avons identifié des centaines de gènes différentiellement méthylés, incluant ceux ayant des fonctions connues dans la douleur, affectant les domaines liés à la réponse au stimulus dans les premiers points de temps, la fonction immunitaire dans les derniers points de temps et la régulation de l'actine et du cytosquelette tout au long de l'observation (Manuscrit I). Cette étude a confirmé l'implication de la méthylation de l'ADN du PFC au cours de l'évolution de la douleur chronique, et a également identifié des changements spécifiques de la méthylation de l'ADN de gènes et domaines liés à la douleur, à certains points temporels.

Pour explorer la réponse de la méthylation de l'ADN aux interventions, la SAM ou l'exercice volontaire ont été dispensés après lésion du nerf sciatique dans deux expériences distinctes. L'administration chronique de SAM, 3 mois après la blessure, a atténué la douleur neuropathique et la méthylation différentielle de plus de 4000 régions génomiques. Ces régions étaient liées aux domaines fonctionnels de la signalisation intracellulaire, de la locomotion et migration cellulaire, de la structure du cytosquelette et de l'adhésion cellulaire (Manuscript II). La possibilité de faire volontairement de l'exercice après la lésion a également atténué la douleur neuropathique et la méthylation différentielle de plus de 5 000 régions génomiques. Ces régions étaient liées aux domaines fonctionnels du transport ionique et de l'homéostasie, de l'adhésion et locomotion cellulaire, du fonctionnement immunitaire et de la morphogenèse (Manuscrit III). Dans chaque expérience, l'intervention thérapeutique a permis d'inverser les changements de méthylation de l'ADN liés à la douleur dans plus de 1000 régions génomiques. Ces études ont confirmé la réactivité de la méthylation de l'ADN du CPF aux interventions au cours de la douleur chronique, et qu'une intervention thérapeutique efficace inverse le statut de méthylation d'un sous-ensemble de gènes affectés par la douleur chronique.

Les travaux présentés dans cette thèse démontrent que la méthylation de l'ADN du CPF est dynamique et sensible au développement de la douleur chronique et aux interventionx thérapeutique efficaces. Ces résultats permettent de mieux comprendre comment la douleur chronique est régulée dans le CPF au cours de son développement et de son traitement, et identifient les domaines fonctionnels principalement affectés par

la méthylation de l'ADN. Cette thèse construit les bases des futures recherches qui exploreront les mécanismes épigénétiques intervenant dans le développement de la douleur chronique et des thérapies futures qui cibleront les mécanismes épigénétiques pour soulager la douleur chronique.

Acknowledgements

This thesis is the accumulation of five years of thought, effort, failure, and ultimately success and would not have been possible without the contributions and support of those who I have been lucky enough to be surrounded by during my degree. Dr. Laura Stone has been an amazing Ph.D supervisor and has guided my scientific and personal growth with good humour, patience, and well-timed applications of alcohol. Laura has provided me the freedom to try things and invest weeks to work on something I believed in, but always with a reminder of the bigger picture and the importance of moving on to the next step. Her belief and support of her students is best reflected by the number of courses, conferences, and meetings I have attended throughout my Ph.D, and her joy in what she does is shared by all of us during the happy hours of those events. I am proud of what we have accomplished in this thesis, and I am incredibly grateful for her guidance and support throughout this journey.

Equally responsible for my growth and success over these past five years has been Dr. Magali Millecamps. Magali performs the thankless task of molding new students into professional scientists, however she has always done so with compassion, humour, and a selfless desire to help others reach their potential. Every one of us has been made better by her efforts, both as scientists and as people, and her advice on science and life has been invaluable. I have immensely enjoyed our “what if” conversations about science and the world, hearing about what thing her sons have done this week, and watching

other new students be put through the Magali process. My thesis would not have been nearly as enjoyable without her guidance and presence.

I would also like to thank the members of my thesis committee for their guidance and advice throughout the years. The combined knowledge and expertise of Dr. Reza Sharif-Naeini, Dr. Luda Diatchenko, and Dr. Etienne Vachon-Presseau have been incredibly valuable, and I have always left our meetings with more refined ideas and an enhanced perspective of my work.

I sit in the centre desk in the Stone Pain Lab, and so have been quite literally surrounded by fantastic people for every day of my Ph.D. HyungMo Kang, Dr. Peter Lee, Dr. Stephanie Gregoire, Lina Naso, Dr. Miyako Suzuki, Dr. Emerson Krock, Brooke Currie, Daniel Foster, Sunny Jang, Raquel Farias, Dr. Yuya Kawarai, Iulia Tufa, and Matthew Mannarino have all contributed to my thesis through their work, advice, and company, and I count myself lucky to have ended up amongst them. I would also like to thank the Szyf Lab and Dr. Moshe Szyf, Dr. Elad Lax, and Dr. Mali Salmon-Divon for their advice and guidance throughout my thesis. In particular, I owe a huge debt of gratitude to Dr. Mali Salmon-Divon for teaching me so much about bioinformatics and being incredibly generous with her time and attention.

This thesis was supported through fellowships and travel awards from the Louise and Alan Edwards Foundations, the Fonds de Recherche du Québec – Santé, the Integrated Program in Neuroscience, the International Association for the Study of Pain, and the Québec Pain Research Network. Operating grants from the Canadian Institutes

of Health Research also provided financial support for my research. I would also like to thank the Canadian Centre for Computation Genomics, Compute Canada, and the Institut de Recherches Cliniques de Montréal for their technical support and expertise.

Finally, I need to thank all those who made life enjoyable outside of the lab and have been a part of my life throughout this thesis. Louise Fonteyne has been the best partner through this thesis and I owe her everything. My friends have been a constant reminder that there is more to life than chronic pain, and there many more ways of enjoying it. My family have been ever-present, and have helped me navigate the beginning, middle, and end of this degree and all of the decisions and difficulties along the way.

Contribution of Authors

This manuscript-based thesis consists of three multi-authored manuscripts. Each manuscript includes several original and distinct contributions to knowledge that will be demonstrated and discussed throughout this thesis. For each manuscript, I (L.Topham) conducted the majority of data analysis design and work, and wrote the initial draft of each manuscript. Each manuscript was a collaborative effort of the authors to design experiments, collect and analyze data, and write and revise the final manuscripts. Below is a categorical list of each author's contribution to each manuscript.

Manuscript I: The Transition from Acute to Chronic Pain: Dynamic Epigenetic Reprogramming of the Mouse Prefrontal Cortex up to One Year Following Nerve Injury

Published in *Pain*, 2020

Study Design: L. Topham, S. Gregoire, M. Millecamps, E. Lax, M. Salmon-Divon, M. Szyf, L. Stone

Conducted In Vivo Experiments and Processed Tissue: S. Gregoire, M. Millecamps, HM. Kang

Analysed Data: L. Topham, HM. Kang

Wrote Manuscript: L. Topham, M. Szyf, L. Stone

Funding: L. Stone, M. Szyf

Manuscript II: Attenuation of neuropathic pain by s-adenosylmethionine is associated with genome-wide reversals of pathological changes in DNA methylation in mouse frontal cortex

In preparation

Study Design: L. Topham, S. Gregoire, M. Millecamps, E.Lax, M. Salmon-Divon, M.Szyf, L. Stone

Conducted In Vivo Experiments and Processed Tissue: S. Gregoire, M. Millecamps, HM. Kang

Analysed Data: L. Topham

Wrote Manuscript: L. Topham, L. Stone

Funding: L. Stone, M. Szyf

Manuscript III: Voluntary exercise attenuates chronic neuropathic pain and reverses nerve injury-induced modifications in DNA methylation in mouse frontal cortex.

In preparation

Study Design: L. Topham, S. Gregoire, M. Millecamps, E.Lax, M. Salmon-Divon, M.Szyf, L. Stone

Conducted In Vivo Experiments and Processed Tissue: S. Gregoire, M. Millecamps, HM. Kang

Analysed Data: L. Topham

Wrote Manuscript: L. Topham, L. Stone

Funding: L. Stone, M. Szyf

List of Abbreviations

1Yr – one year post-injury

5hmC – 5-hydroxymethyl cytosine

5mC – 5-methylcytosine

ACC – anterior cingulate cortex

CpG – cytosine guanine sequence

D1 – one day post-injury

DLPFC – dorsolateral prefrontal cortex

DM – differentially methylated

DNMT – DNA Methyltransferase

DRG – dorsal root ganglia

FDR – false discovery rate

HAT – histone acetyltransferase

HDAC – histone deacetylase

HMT – histone methyltransferase

LTD – long term depression

LTP – long term potentiation

M6 – six months post-injury

mPFC – medial prefrontal cortex

PAG – periaqueductal grey

PFC – prefrontal cortex

S1 – primary somatosensory cortex

S2 – secondary somatosensory cortex

SAM – s-adenosylmethionine

SNI – spared nerve injury

TET – ten-eleven translocation enzyme

TSS – transcription start site

W2 – two weeks post-injury

Chapter 1: Introduction

2.1. The Challenge of Chronic Pain and the Potential of Epigenetics

Chronic pain is a global challenge, affecting 10-20% of adults worldwide at any given time and with 80% of people experiencing some form of chronic pain during their lifetime. Chronic pain stretches across all socio-economic levels and as of 2016, was the leading cause of years lost to disability in both men and women [1-3]. The high prevalence of chronic pain leads to massive healthcare costs with billions spent yearly on its treatment, and billions more lost indirectly through missed days of work and resource opportunity cost [4, 5]. Individuals living with chronic pain also suffer from one of the poorest qualities of life among chronic conditions [6]. Individuals report poorer mental health and sleep, difficulties maintaining personal relationships, reduced productivity at work and are commonly comorbid for depression, anxiety, and cognitive deficits [7]. These factors exacerbate suffering, prolong recovery, and make chronic pain complex and difficult to treat.

One of the key aspects that differentiates the experience of chronic pain from acute pain is the greater impact of these cognitive components [8]. Both human pain patients and animal models report deficits in decision making, attention, working memory, and executive function [9-13]. The prefrontal cortex (PFC) is one of the key structures mediating these processes, and undergoes significant functional and anatomical remodeling during chronic pain in both human and animal populations [14-20]. Animal models have also noted widespread changes in PFC gene expression during chronic pain [21-23]. This combination of PFC remodelling and cognitive/affective comorbidities has

been proposed to contribute to chronic pain intractability and make it difficult to resolve chronic pain. However if chronic pain is successfully attenuated through treatment, PFC remodelling can be reversed in human pain patients [24-26]. The PFC's plasticity in response to pain combined with the observed genome-wide changes in expression implicate epigenetics as a potential regulatory mechanism.

Epigenetics refer to stable but malleable mechanisms of influencing gene expression, including histone modifications, chromatin conformation, and DNA methylation. These modifications regulate much of cellular differentiation during development, and crucially they remain responsive to environmental changes throughout life [27]. Stress, nutrition, behaviour, physical activity, and environmental pollutants have all been found to induce the epigenetic regulation of gene expression and lead to altered phenotypes [28]. Therefore, epigenetics are a mechanism by which the environment, including pain stimuli, can directly modulate and affect gene expression.

Given the difficulty of treating chronic pain and the limited development of novel therapies in recent years, examining the relationship between chronic pain and PFC epigenetics provides a twofold benefit. First, by understanding the epigenetic response to chronic pain, we can identify potential epigenetic mechanisms to target or manipulate in order to prevent the development and maintenance of chronic pain. Second, by examining the genome-wide epigenetic response to pain, we can observe which cellular functions are being differentially regulated and identify new genes and domains that may yield new therapeutic avenues.

2.2. Comprehensive Literature Review and Background

2.2.1. **Pain Pathways**

Pain is defined by the International Association for the Study of Pain (IASP) as “an unpleasant sensory and emotional experience associated with, or resembling that associated with, actual or potential tissue damage” [29]. Pain sensation, perception, and experience involves the entire nervous system starting with peripheral detection, progressing through spinal processing and modulation, and then ascending to supraspinal perception and interpretation.

2.2.1.1. Peripheral and Spinal Pain Transduction

Most pain begins as the peripheral detection of a nociceptive stimulus, that is, an actual or potential tissue damaging event. Nociceptive stimuli can be noxious thermally, mechanically, or chemically, and are detected by specialized peripheral sensory neurons called nociceptors. These afferent nociceptive signals are conducted by either Aδ or C-fibers of the dorsal root ganglia (DRG) from the peripheral nociceptors to the dorsal horn of the spinal cord. Aδ fibers are myelinated, transmit noxious mechanical or thermal stimuli, and terminate primarily either in lamina I and the outer layer of lamina II, or arborize throughout lamina II-V [30, 31]. C fibers are unmyelinated, terminate primarily in laminae I and II, and transmit noxious mechanical, chemical or thermal stimuli as well as itch. C fibers can be broadly classified into peptidergic and non-peptidergic subtypes, which have been proposed to mediate the perception of heat pain and mechanical pain respectively [32]. Once arriving at the dorsal horn, Aδ and C-fibers synapse with interneurons or ascending projection neurons. Interneuron signalling within the dorsal

horn is complex and serves to modulate and potentiate nociceptive signalling. Broadly, interneurons are excitatory or inhibitory, and can mediate allodynia and gate pain sensation [33-35]. Ascending projection neurons transmit nociceptive information to supraspinal structures, primarily ascending via the anteriolateral spinothalamic tract to the thalamus. However, projection neurons also travel via the spinoparabrachial-amygdala pathway to the lateral parabrachial nuclei and amygdala, and via the spinoreticular pathway to the periaqueductal grey (PAG).

2.2.1.2. Supraspinal Pain Circuits

From the lateral spinothalamic tract and thalamus, nociceptive information is sent to the primary (S1) and secondary (S2) somatosensory cortices, insula, and anterior cingulate cortex (ACC). Projections from the lateral parabrachial nuclei route nociceptive stimuli to the amygdala and subsequently to the basal ganglia. The dorsolateral (DLPFC) and medial prefrontal cortex (mPFC) integrate inputs from S1, S2, insula, ACC, amygdala, and basal ganglia [36, 37].

Human and animal studies have identified how each supraspinal area contributes to the perception and interpretation of nociceptive stimuli. The S1 and S2 cortices are responsible for the localization, intensity, and duration of pain [38, 39]. The ACC primarily encodes the aversive emotional and affective dimensions [40, 41], while the insular cortex is involved in both pain sensation and pain affect [42]. In humans, the DLPFC and mPFC are crucial as integrators of ascending sensory information, cognitive and emotional responses, and descending inhibitory control during pain [37]. Human research has linked DLPFC activity with pain suppression and maintenance of pain inhibition and has

hypothesized it to be a “pain control centre”. Bilateral DLPFC activation occurs during intentional pain suppression, is associated with reduced unpleasantness of pain, and is involved in mediating placebo effects on pain [43-45]. Greater connectivity between right and left DLPFC is correlated with greater pain tolerance while conversely, reduced bilateral DLPFC activity is correlated with increased pain catastrophizing during pain [46, 47]. In contrast to DLPFC, mPFC is more involved in the processing of negative emotions and appraisal of unfavourable outcomes in relation to oneself. mPFC activity is correlated with sustained high-intensity pain and pain intensity [48]. The rostral ACC is a subregion of mPFC and contributes to mPFC encoding of aversive stimuli. Rostral ACC, mPFC, and amygdala work together to encode aversive memories and may be involved in pain-related memory acquisition and extinction [36].

Through descending pathways, supraspinal structures modulate pain processing and transduction. The frontal cortices and ACC can act via the periaqueductal gray to attenuate pain sensation during placebo and the expectation of pain relief [45, 49]. Conversely, signalling via the rostral ventromedial medulla can facilitate pain and is required for maintaining central sensitization in the spinal cord [50].

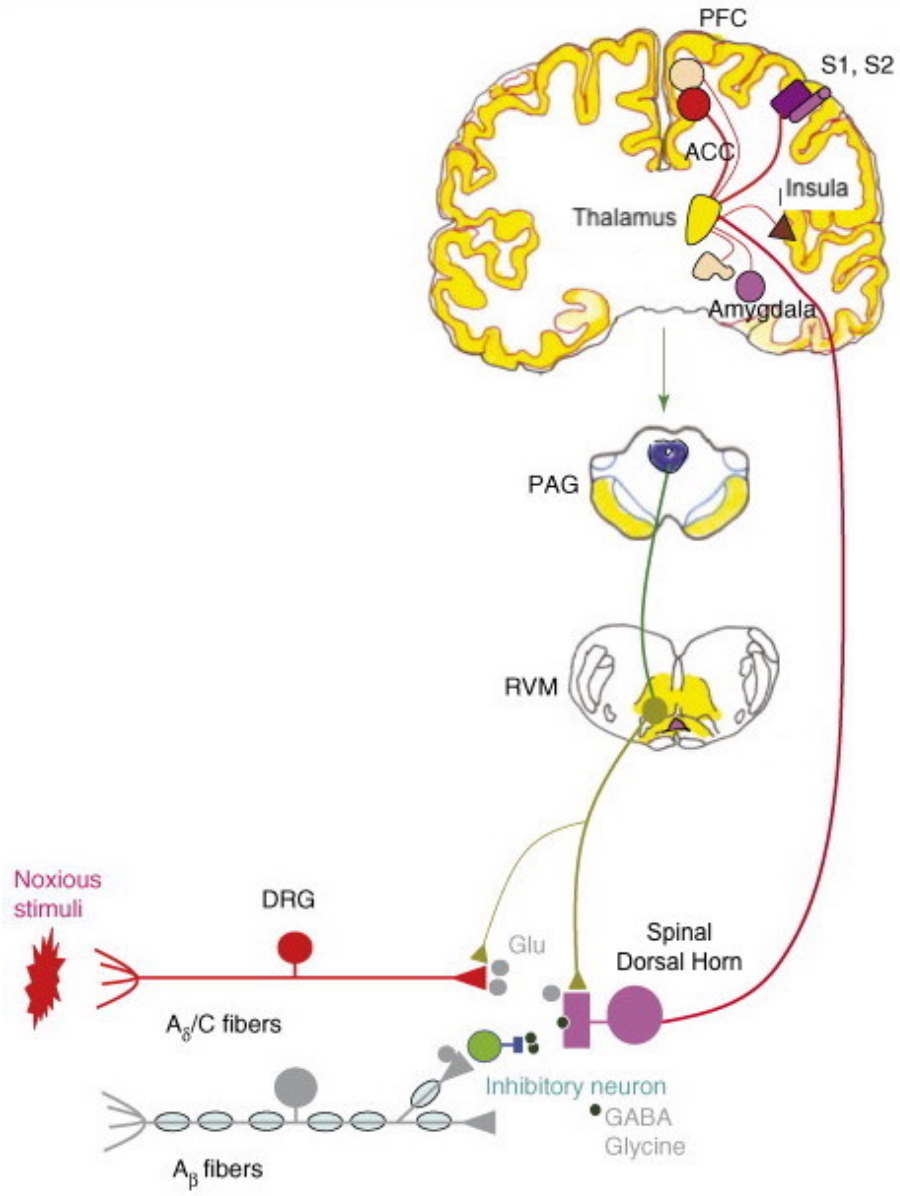

Figure 1: Nociceptive information is detected in the periphery and carried to the dorsal horn of the spinal cord by primary nociceptive afferents. Once in the dorsal horn, inhibitory interneurons and descending fibers modulate nociceptive information before it ascends to supraspinal areas. Supraspinal structures mediate pain perception and emotional and cognitive processing of nociceptive information. This image was adapted from [51], and used with permission of the publisher.

2.2.2. **Chronic Pain**

IASP has defined that for human patients, once pain has persisted or recurred for more than 3 months, it is considered to be chronic. Chronic pain can be considered a disease on its own, when it occurs as the sole or primary complaint, or as secondary and a symptom of another disease, such as cancer or trauma [52]. Animal models have revealed a number of mechanisms that underlie chronic pain syndromes. The use of animal models provides better control over the time course and development of chronic pain, and more consistent presentations of chronic pain between subjects. Neuro- or peripheral inflammation, and peripheral and central sensitization are mechanisms that most chronic pain syndromes have in common, all of which can lead to enhanced pain sensation.

Immune cells and nociceptors are mutually responsive, with each capable of modulating and enhancing each other's activity. Animal models have observed that the secretion of pro-inflammatory mediators by immune cells such as nerve growth factor (NGF), tumor necrosis factor alpha (TNF-α), and interleukin 1-beta (IL-1β) can lead to increased sensitization of peripheral nociceptors and central neurons [53]. In turn, peripheral and central neurons can attract and activate local and circulating immune cells through neurogenic secretion of chemokines such as CCL2 [54].

Peripheral sensitization is the reduced activation threshold and increased membrane excitability of peripheral nociceptors. Peripheral sensitization is responsible for primary hyperalgesia, pain hypersensitivity located at the site of damaged or inflamed tissue. Peripheral sensitization is driven by increased insertion or changes in sensitivity

of transducer and voltage-gated ion channels into nociceptor membranes, triggered by inflammatory mediators [55]. Central sensitization is the increased responsiveness of central nociceptive neurons to afferent input.

Central sensitization contributes to secondary hyperalgesia and allodynia, defined as pain hypersensitivity in non-inflamed or non-damaged tissue, and pain sensitivity to sub-threshold stimulation respectively. Central sensitization is mediated in part by the increased activity and density of AMPA and NMDA receptors in the post-synaptic membrane of dorsal horn neurons, leading to heightened excitability to afferent input. Loss of inhibitory GABAergic or glycinergic signalling from dorsal horn interneurons also can contribute to central sensitization [56]. Central sensitization can occur independently of peripheral input, with central lesions driving central sensitization and subsequent peripheral pain sensitivity [57, 58]. In this thesis, we will focus on **chronic peripheral neuropathic pain** as the primary chronic pain syndrome.

2.2.2.1. Peripheral and Spinal Mechanisms and Response

Neuropathic pain is characterized in human pain patients by spontaneous burning and electric shock like sensations, and neuropathic pain remains difficult to treat due to the heterogeneity of potential etiologies [59]. Peripheral neuropathic pain arises from damage to peripheral afferents through diseases such as diabetes or direct trauma. This damage generally results in the ectopic generation of action potentials along damaged and neighbouring nociceptive afferents. Animal models show that this ectopic nerve activity is predominantly driven by the abnormal expression and activity of voltage-gated sodium channels, with dysregulation of potassium channels and transport contributing to

altered membrane excitability [60-63]. The ongoing activity of peripheral afferents is associated with increased presynaptic release of glutamate in the dorsal horn through increased expression of voltage-gated calcium channels and the loss of inhibitory G-protein coupled receptors such μ-opioid receptors [64, 65]. Post-synaptic activity is also sensitized through the increased activity and expression of AMPA and NMDA receptors, and a number of calcium induced signalling pathways that initiate synaptic plasticity [66-68]. Central sensitization and hyperexcitability in the dorsal horn is also potentiated by the loss of GABAergic interneurons in the dorsal horn [69, 70].

Nerve lesions also initiate peripheral and central inflammation mechanisms which potentiate aberrant signalling. Immune involvement in neuropathic pain is complex as macrophages and microglia can promote both pro-inflammatory, pro-nociceptive or anti-inflammatory, pro-recovery responses. Peripheral nerve injury results in macrophage infiltration, T cell activation, and the expression of pro-inflammatory cytokines at the site of injury. In vivo animal models demonstrate pro-inflammatory cytokines can directly sensitize and induce ectopic signalling in primary nociceptive afferents [71, 72]. Microglia in the dorsal horn perform a similar function to macrophages, becoming activated after nerve injury and secreting pro-inflammatory cytokines. Microglial surface receptors such as P2X4, P2X7, and toll like receptors (TLRs) initiate the release of cytokines including brain derived neurotrophic factor (BDNF), TNF-α, and IL-1β. These cytokines increase excitatory nociceptive neuron activity by increasing the strength of excitatory glutamatergic signalling, and disinhibition via elevated intracellular chloride levels on inhibitory neurons [73-76].

2.2.2.2. Supraspinal Mechanisms and Response

Human studies have revealed that continued nociceptive afferent input and central sensitization of the dorsal horn results in increased ascending excitatory signalling to supraspinal structures and altered pain circuit activation and physiological response [77-80]. Broadly, supraspinal pain processing is thought to transition away from the sensory-discriminative circuit that is predominant in acute pain, involving S1, S2, and insula, and towards an emotional-affective circuit in chronic pain, involving prefrontal cortex, amygdala, and ACC [36, 78]. The duration of pain also contributes to the degree of change observed in supraspinal circuits [80, 81]. While many supraspinal structures undergo physiological and functional changes, this thesis will focus on the **prefrontal cortex**.

2.2.2.3. Prefrontal Cortex Pain Mechanisms and Response

During chronic pain, human PFC is abnormally active and shows altered functioning compared to normal brain functioning during acute pain [82]. DLPFC activity is normally inversely correlated with pain sensation in healthy individuals, however in fibromyalgia [83], this correlation is disrupted. mPFC normally shows activation in response to painful stimuli, however in chronic pain this activation is enhanced [48, 84]. Even in the absence of painful stimuli, during chronic pain the PFC shows abnormal functional connectivity with multiple regions involved in the default mode network [85]. This abnormal activity is accompanied by widespread functional and anatomical reorganization in response to chronic pain.

Broadly, after the onset of chronic pain, a number of imaging studies have detected the loss of grey matter in PFC. Human studies of chronic pain reveal losses in DLPFC and mPFC in back pain [17, 19, 82, 86-88] , fibromyalgia [15], osteoarthritis [26], migraine [89], visceral pain [90, 91], and neuropathic disorders [92]. Despite differing paradigms in grey matter measurement like grey matter density or volume, or cortical thickness, these studies all display some grey matter loss. Grey matter decrease is not uniform across PFC areas or to the same degree, however this could be expected given the heterogeneity of the evaluated pain disorders, variable duration of chronic pain, and interindividual differences. The degree of PFC grey matter loss is correlated in some conditions with ratings of pain intensity and with pain duration [15, 82, 93-95].

The abnormal activity and grey matter loss observed in human studies is replicated in rodent models of chronic pain. When translating human studies to rodents, it should be noted that rodents lack a human-equivalent DLPFC, however rodent mPFC is thought to be anatomically similar and mediate similar attention, working memory, and decision making processes [96, 97].

Functional imaging studies of rodent models first observe abnormal activity in PFC 28 days post-injury and in some cases up to 4 months [98, 99]. Detecting the loss of PFC grey matter by structural MRI can take 3-4 months [20]. However, molecular and electrophysiology studies have found altered synapse signalling and formation in mPFC as soon as one week after induction of a pain model. One to two weeks after neuropathic injury, pyramidal neurons in layers 2/3 of mPFC have larger basal dendrites and spine density, enhanced presynaptic release of glutamate, and postsynaptic AMPA, NMDA,

and HCN current, correlated to the degree of pain hypersensitivity [99-102]. Metabotropic glutamate receptor mGluR5 is also elevated in rat mPFC 4-6 months after neuropathic injury, with pharmacological inhibition capable of ameliorating pain hypersensitivity and overexpression inducing pain in naïve animals [103]. Concurrently, layer 5 mPFC pyramidal neurons show a decrease in response to glutamatergic input [104, 105]. This decreased response may be a result of GABAergic interneuron feed forward inhibition, with increased GABAergic signalling correlated with increased neuropathic pain and vice versa [106]. The precise causes of these circuit level changes in mPFC signalling have yet to be determined. They may be the result of layer specific input from other brain areas, such as hippocampus and amygdala [107, 108].

The root mechanisms of grey matter loss remain unclear. An initially proposed mechanism was cellular death or atrophy as a result of excitotoxicity [37]. Neuronal loss can be demonstrated by decreased concentrations of neuronal marker N-acetyl-aspartate (NAA), however results are mixed with some studies finding decreased NAA [109-111], while others do not find any differences between healthy and chronic pain individuals [112].

An interesting component of chronic pain-related changes in PFC is the reversal of grey matter loss when an intervention successfully attenuates pain. In human pain patients, surgical interventions that reduce pain result in increased DLPFC and ACC grey matter at patient follow up 4 and 6 months post injury [25, 26, 113]. If the source of pain resolves naturally without any outside intervention, this is also sufficient to reverse pain related losses of grey matter [86, 114]. Finally, cognitive interventions designed to reduce

the anticipatory fear and emotional impact also increased DLPFC and ACC grey matter and reduced reports of pain symptoms and pain experience [24]. The reversibility of chronic pain related maladaptive changes in grey matter has also been demonstrated in animal models, where pain relief following treatment with metformin restores axon initial segment length in layer 5/6 of the infralimbic cortex and reverses pain related cognitive impairment [115].

Given the reversibility of grey matter losses after successful pain attenuation, widespread PFC cell death is unlikely to be the primary mechanism underlying grey matter loss. While the mechanisms underlying grey matter loss remain unknown, hypotheses include a widespread loss of synapses mediated by glia or long-term depression resulting from excessive neuronal excitation [26, 116, 117], changes in PFC microvasculature [95, 118], or changes in extracellular fluid volume [113]. Similarly, the mechanisms underlying the recovery of grey matter after intervention are also unknown. Grey matter recovery may occur via a functional reversal of the mechanisms that were initially responsible for grey matter loss, or may involve entirely new functional pathways.

2.2.2.4. Therapeutic Interventions Against Chronic Pain

Therapeutic interventions against chronic pain have progressed through multiple phases as clinical and basic science have made additional discoveries regarding mechanisms underlying chronic pain. Opiates, particularly morphine, were and are the gold standard for relieving acute pain. However, their use in chronic pain has diminished as clinicians have become more aware of their strong addictive potential and long-term risks [119, 120]. Opiates are effective because they mimic endogenous opioid peptides

and act upon endogenous opiate receptors, in particular the μ-opioid receptor. The PAG plays an important role by activating descending inhibition of pain through the rostral ventral medulla to spinal cord [121]. Morphine analogues such as buprenorphine or opioid receptor agonists such as tramadol or methadone are more commonly prescribed to better manage the risk of addiction, respiratory depression, and gastrointestinal side effects, however these side effects remain a concern [122].

Non-steroid anti-inflammatory drugs (NSAID) and selective COX-2 inhibitors are targeted at reducing pro-inflammatory responses to reduce pain. NSAIDs benefit from limited abuse potential and relatively safe risk/benefit profiles. The basic mechanism of action of NSAIDs is to inhibit cyclooxygenase 1 or 2 and prevent prostaglandin-mediated inflammation [123]. However, NSAIDs increase risk of nephro- and gastrointestinal toxicity with chronic use, and place immunocompromised patients and the elderly at particular risk for opportunistic infections [124]. Moreover, their anti-inflammatory mechanism of action limits their efficacy to treating inflammatory chronic pain conditions like osteo- or rheumatoid arthritis, or mild to moderate presentations of other chronic pain disorders.

Tricyclic and serotonin-norepinephrine reuptake inhibitors (SNRIs) anti-depressants are often utilized and may simultaneously address chronic pain and depression. Tricyclic anti-depressants have well documented effects against chronic pain and are particularly recommended against neuropathic pain [125, 126]. Interestingly, anti-depressants still inhibit pain when the patient is not in a depressive state, and mediate their analgesic effect faster than their anti-depressive effect [127, 128]. A proposed

mechanism is the action of inhibited reuptake of noradrenalin on α_2-adrenergic receptors in the dorsal horn of the spinal cord. Pre-synaptically, this action inhibits voltage-gated calcium channels from initiating the release of excitatory neurotransmitters and post-synaptically, it may open inward rectifying K^+ channels causing hyperpolarization [129]. Other mechanisms include NMDA and AMPA receptor inhibition [130], increased GABA-B receptor function [131], and sodium channel blockade [132].

Pharmacological treatments have demonstrated effectiveness in reducing chronic pain, however many of them act to reduce pain sensation but do not treat the underlying cause. Moreover, many of these treatments have negative side-effects with prolonged use. Other pharmacological interventions that were not discussed here include gabapentin and pregabalin, anti-psychotics, other anti-convulsants, benzodiazepines, and cannabinoids.

Cognitive and mind-body based techniques have been introduced as non-pharmacological interventions against chronic pain and include cognitive behavioural therapy (CBT), meditation, hypnosis, and relaxation. These interventions are varied and do not have a unified protocol. Most techniques focus on controlling a cognitive component such as attention or problem solving, and an emotional component such as distress or anxiety awareness and reduction [133]. CBT and meditation have significant but small effects on pain and disability, and moderate effects on mood and catastrophizing compared to non-treatment controls. However when compared to active treatment such as pharmacological intervention or physical therapy, CBT and mediation only confer significant improvements to catastrophizing and ratings of disability [134].

CBT or mediation practitioners have lower pain unpleasantness ratings correlated with stronger ACC and ventromedial PFC activity [135]. Crucially, practitioners do not have to be actively meditating to benefit from lower rated pain unpleasantness, suggesting that meditation and CBT confer persistent changes. As mentioned above, CBT can reverse chronic pain induced losses in grey matter [24]. Follow up research is needed to dissect which elements of CBT are most effective, and if certain chronic pain disorders or certain patient populations benefit more from one element of CBT or another.

Exercise and movement interventions are other commonly prescribed non-pharmacological interventions. Exercise interventions include aerobic, strength, flexibility or core and balance training programs, as well as yoga, tai chi, and Pilates. However, exercise interventions are greatly varied and can focus on different aspects and levels of physical fitness, which can result in varying levels of pain reduction. However physical activity generally reduces pain, has a variable effect on mood and quality of life, and improves physical functioning [136]. Clinicians and physiotherapists must tailor exercise protocols to the specific presentation of chronic pain. However even low-to-moderate intensity exercise (50-60% of maximum heart rate) is sufficient to improve pain sensitivity and is recommended for certain conditions instead of strenuous exercise [137-139]. The mechanisms of exercise-based pain attenuation remain unclear. Exercise can improve poor sleep, reduce reported depression, and can promote the release of anti-inflammatory cytokines over pro-inflammatory cytokines in chronic pain individuals [140-142].

2.2.3. **Epigenetics**

Epigenetics refers to a group of mechanisms that alter the phenotype of a cell or organism without modifying the genotype. Epigenetic mechanisms allow for stem cells with the same genome to differentiate along different cell type fates. Epigenetics represent a mechanism that can enact stable and long-term changes in response to developmental or environmental signals [143]. Epigenetic changes are mitotically heritable, meaning daughter cells will express the same phenotype that their mother cells developed. There is also evidence for epigenetic changes to be meiotically heritable, allowing for the parental environment to shape and alter offspring phenotype [144]. Epigenetic regulation occurs via three predominant interrelated mechanisms: DNA methylation, histone modification, and chromatin conformation. In this thesis, we will focus on **DNA methylation** as the primary epigenetic mechanism.

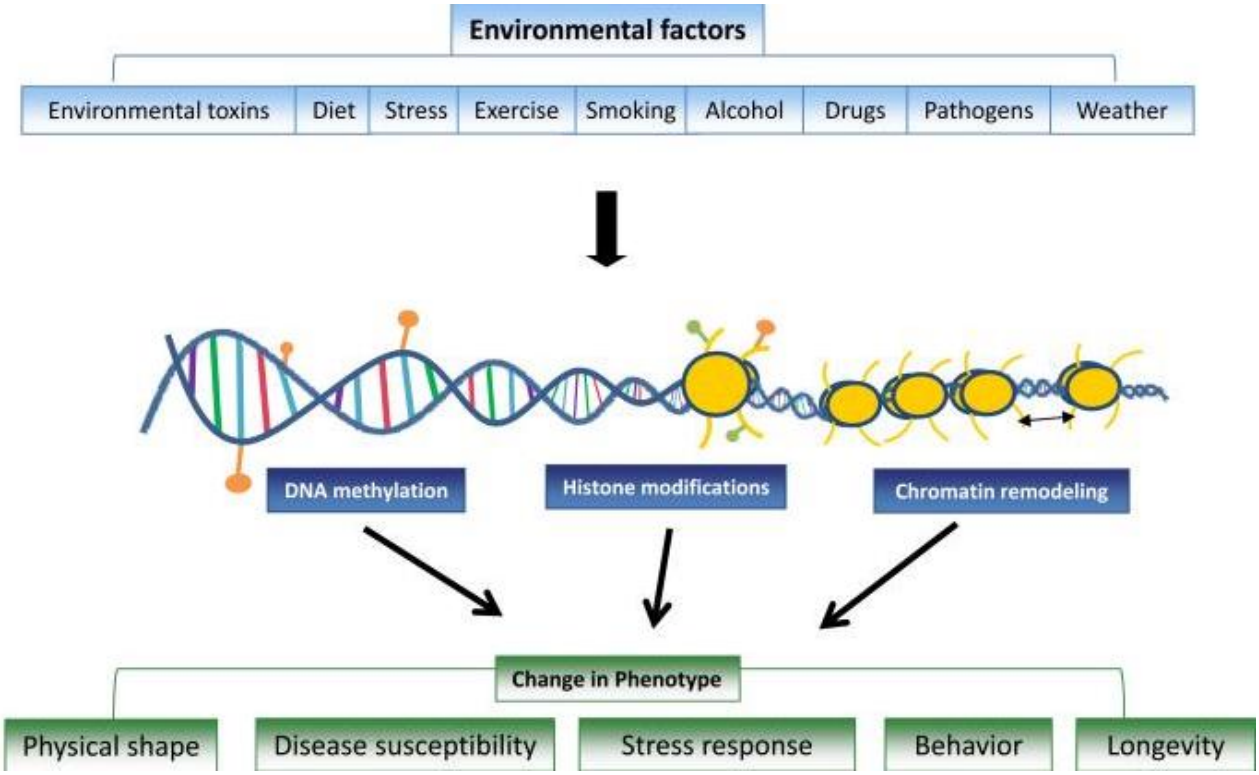

Figure 2: Epigenetics mediates the effect of environmental factors and can induce stable and long term changes in phenotype. This image was adapted from [145], and was used with permission from the publisher.

2.2.3.1. DNA Methylation

DNA methylation is the direct chemical modification of a DNA nucleotide. In differentiated eukaryote cells, DNA methylation primarily occurs on cytosine nucleotides in a dinucleotide cytosine guanine sequence (CpG) [146]. In these cells, ~80% of the available CpG sites are methylated [147]. The basic methylation mechanism involves the covalent transfer of a methyl group from the universal methyl donor, s-adenosyl methionine (SAM), to the 5' carbon of a cytosine nucleotide to form 5-methylcytosine (5mC) [148]. DNA methylation occurs as either maintenance methylation, that is, faithful replication of methyl marks from parent to daughter DNA strands during mitosis, or *de novo* methylation, which is the novel placement of methyl marks on available CpG positions.

2.2.3.1.1. DNA Methylation Mechanisms

The addition of methyl groups to cytosine nucleotides is mediated by DNA Methyltransferases (DNMTs). At present, six DNMT enzymes have been identified: DNMT1, DNMT2, DNMT3a, DNMT3b, DNMT3c, and DNMT3L. DNMT2 is a tRNA methyltransferase, while DNMT3c thus far is believed to be specific to male murine germ cells, therefore they will not be discussed further [149, 150]. DNMT1, 3a, and 3b all share a conserved catalytic domain responsible for performing methyltransferase activity. DNMT1 is responsible for maintenance methylation and is the most abundantly expressed DNMT in mammalian cells. DNMT1 is localized to the replication fork during S-phase and binds with UHRF1, which targets DNMT1 to methylate hemi-methylated DNA [151]. In contrast, DNMT3a and 3b are responsible for *de novo* methylation [152].

There are exceptions to this division of labour between DNMT1 and DNMT3a and 3b [153-155], however the above model is the general rule. The mechanisms for targeting DNMT3a and 3b *de novo* methylation are complex and may involve multiple overlapping systems. DNMT3a and 3b both form a complex with DNMT3L, however they target different genetic loci. DNMT3a preferentially targets DNA marked by unmethylated histone 3 lysine 4 tails (H3K4), and prefers CpG sites with a CG(C/T) motif [156-159]. In contrast, DNMT3b preferentially targets DNA marked by trimethylated histone 3 lysine 36 (H3K36me3) and trimethylated histone 3 lysine 9 (H3K9me3), and prefers CpG sites with a CG(G/A) motif [158, 160, 161]. In development, DNMT3a is required for *de novo* methylation at transcription start sites (TSS), while DNMT3b predominantly acts upon the X chromosome [161]. Finally, DNMT3L is an important regulatory co-factor of DNMT3a and 3b. DNMT3L is catalytically inactive, however as mentioned above, it forms a complex with DNMT3a and 3b, enhances their methylation activity, and is crucial for appropriate targeting of methylation [162, 163].

The removal of methyl groups from DNA can occur via two active mechanisms First, 5mC bases can spontaneously deaminate and convert to thymine, at which point they are identified and removed via base excision repair [164]. The second and more common mechanism is via ten-eleven translocation (TET) enzymes. TET enzymes perform iterative oxidation to convert 5mC through a series of intermediaries in order: 5-hydroxymethyl cytosine (5hmC), 5-formyl cytosine (5fC), and 5-carboxyl cytosine (5caC) [165-167]. The enzyme thymine DNA glycosylase (TDG) recognizes 5fC and 5caC and excises them to allow cytosine to be reinserted via base excision repair [168, 169]. There

are three main TET enzymes, TET1, TET2, and TET3. TET enzymes have a number isoforms that limit its expression or activity to specific tissues or developmental phases. TET1s is the dominant TET1 isoform in mouse somatic tissue and TET1 mediates activity-induced DNA demethylation in mouse neuronal tissue [170, 171]. TET3 isoform TET3FL is thought to preferentially target TSS CpG islands in neuronal tissue and maintain their unmethylated state [172].

2.2.3.1.2. Regulatory Role

DNA methylation can occur at any CpG site within the genome, and indeed, 70~80% of the genome is methylated in differentiated somatic cells. In gene promoters, DNA methylation is associated with a repressed and closed chromatin conformation and inhibition of gene expression [173]. In promoter regions with a low CpG content, DNA methylation rapidly results in gene repression [174]. However, other promoter regions contain CpG rich sequences called CpG islands that are frequently unmethylated, and have low rates of CpG mutation [175]. In fact, nearly 70% of all promoters have a CpG island [176], and 50% of all CpG islands are associated with a TSS [177]. CpG islands are actively demethylated and serve to enhance promoter function by increasing DNA strand accessibility and allowing transcription factors to bind [175, 178]. DNA methylation outside of promoters can also influence gene transcription. Enhancers are distal regulatory elements that can enhance gene transcription through transcription factor binding and recruitment of co-activators [179]. DNA methylation at enhancers is also associated with repressed gene expression [180, 181]. Conversely, gene body DNA methylation is associated with increased transcription [182, 183].

DNA methylation inhibits gene expression via two primary mechanisms. First, methylated cytosine can sterically interfere with DNA-binding transcription factor recognition of their target sequence [184, 185]. Accordingly, mammalian transcription factor binding sites tend to be more CG rich than the genome [175]. Second, the recruitment of methyl-binding proteins can initiate repressive mechanisms [186, 187]. DNA methylation is recognized by three families of methyl binding proteins: MBD, UHRF, and zinc-finger proteins. The function of the UHRF family is outlined above, and targets DNMT1 to hemi-methylated DNA. The zinc-finger proteins include Kaiso, ZBTB4, and ZBTB38, and they act to repress DNA transcription by binding to methylated DNA [188-190]. However, the MBD family is the best characterized and consists of MBD1, MBD2, MBD3, MBD4, and MeCP2. MBD1, MBD2, and MeCP2 can bind directly to methylated DNA and may have specific preferences for different methylated sites across the genome [191]. MBD3 lacks the ability to bind methylated DNA, and MBD4 acts as a base excision glycosylase specific for thymine [187]. These zinc-finger and MBD proteins recruit various repressor complexes that contain histone methyltransferases (HMT), histone deacetylases (HDAC), DNMTs, and chromatin remodelling proteins that work together to repress gene transcription [173, 192-195].

Genome methylation is profoundly and globally altered during development and differentiation, and then undergoes smaller local modifications across the lifespan in response to environmental stimuli. Broadly, during development there is an initial global demethylation of the genome after fertilization and formation of the blastocyst. After implantation and as embryonic stem cells begin to differentiate along their cell fates, DNA

methylation increases as unnecessary cellular functions are repressed [196]. DNA methylation resulting from differentiation is highly stable, such that 70%-80% of methylated DNA will not change methylation status afterwards [197]. Outside of development, there is a large body of evidence linking changes in DNA methylation in response to environmental stimuli. Changes in DNA methylation are documented after stress, chronic pain, addiction, nutritional changes, physical exercise, exposure to pollutants, and a number of other sources [28, 198-200]. The mechanisms that differentially methylate specific genes in response to environmental stimuli are still unknown. One hypothesis points to the direct action of environmental chemicals on DNMT or TET activity or reducing the availability of SAM. The transcription factor occupancy hypothesis proposes that transcription factor binding enables or prevents DNMT to methylate specific sites by controlling access to target DNA. Via this mechanism, environmentally stimulated transcription factors would bind to their target sequences and preserve an unmethylated state to allow for continued gene expression [201, 202].

2.2.3.2. Other Epigenetic Mechanisms

2.2.3.2.1. Histone Modifications

Histones are octamer protein complexes composed of four subunits, H2A, H2B, H3, and H4, that organize DNA into nucleosomes and allow DNA to be compacted into condensed chromatin. Histones have protruding tails where post-translational modifications are placed to signal and modulate chromatin structure and DNA activity and accessibility. Modifications include methylation, acetylation, phosphorylation, ubiquitination, SUMOylation, and citrullination. Three positions of the H3 subunit tail at

lysine 4 (H3K4), lysine 9 (H3K9), and lysine 27 (H3K27) have the most well studied relationships with DNA methylation, gene expression, and chromatin structure. H3K4 trimethylation (H3K4me3) marks the TSS of active genes and is positively correlated with gene expression [203]. H3K4 monomethylation (H3K4me1) is associated with enhancers, with the presence or absence of H3K27 acetylation (H3K27ac) denoting active or primed enhancers, respectively [204]. H3K4me1 and H3K4me3 marks are associated with open or euchromatin, and prevent promoter and enhancer DNA methylation by inhibiting DNMT3L interaction with H3K4 [159].

Conversely, H3K9 trimethylation (H3K9me3) and H3K27 trimethylation (H3K27me3) are markers for closed or heterochromatin formation and gene repression. H3K9me3 marks constitutive heterochromatin, the conserved repeat-rich genomic regions at centromeres and telomeres that are resistant to transcription factors [205]. H3K9 methylation is mediated by the HMTs SETDB1, Suv39h1/2, G9a and GLP [206]. H3K27me3 marks facultative heterochromatin, the cell-type specific repression of lineage inappropriate genes that remain accessible to transcription factors [207]. H3K27 methylation is mediated by the Polycomb complex PRC2 and its methyltransferases EZH1 and EZH2 [208]. Constitutive heterochromatin maintains genomic structure and stability, while facultative heterochromatin is the counterbalance to euchromatin and serves to stably repress target genes.

Histone acetylation is a general marker for active gene expression. H3K4 acetylation (H3K4ac) is generally found in the promoter and actively transcribed regions of genes, while H3K9 acetylation (H3K9ac) and H3K27 acetylation (H3K27ac) are located

around the TSS [209]. Histone acetylation is performed by histone acetyltransferases (HAT) and removal of acetyl groups is performed by HDACs. Numerous other histone marks such as H3K9me1, H3K27me1, H3K36me3, H3K79me1, H4K20me1, or H3K79me3 and H4K20me3 contribute to the nuanced activation or repression of gene expression respectively [210, 211].

2.2.3.2.2. Chromatin Conformation

As demonstrated above, local open or closed chromatin structure mediated by histone modifications can regulate gene expression. However, the higher-order supramolecular chromatin structure also can promote or repress gene expression. Euchromatin and heterochromatin are organized into distinct regions in the nucleus, with heterochromatin localized to the periphery and nucleolus, and euchromatin localized to the region in between [212]. As chromatin changes between euchromatin or heterochromatin, these open or closed chromatin regions are relocalized to the appropriate area [213]. By localizing euchromatin to a central region, distal enhancers are able to loop around and contact their target promoters and promote gene expression [214]. Regions with a high frequency of interactions are called topologically associated domains (TAD). TADs can prevent or promote enhancer and promoter interaction, and can prevent euchromatin reverting to heterochromatin. The DNA-binding protein CCCTC-binding factor (CTCF) delineates and regulates loops within TADs and works with cohesin to promote and mediate enhancer-promoter interactions by altering loop size. Active transcription of genes can also help delineate TADs [212].

2.2.3.3. Epigenetic Interactions

Despite the separate discussion of the above mechanisms, all epigenetic elements are closely interrelated and reciprocally mediate each other. It is difficult to place these mechanisms in a regulatory hierarchy as DNA methylation and histone modifications simultaneously depend on and alter each other [215, 216]. In some cases, histone status initiates DNA methylation [217], whereas in others DNA methylation changes histone modifications [218]. Co-repressor complexes like Sin3 or NuRD are composed of MBDs, HDACs, HMTs, and possibly DNMTs, which all act to induce and maintain a closed chromatin conformation [219]. Despite being currently unable to answer the epigenetic chicken or egg, what is certain is that these mechanisms work in tight concert to control gene expression.

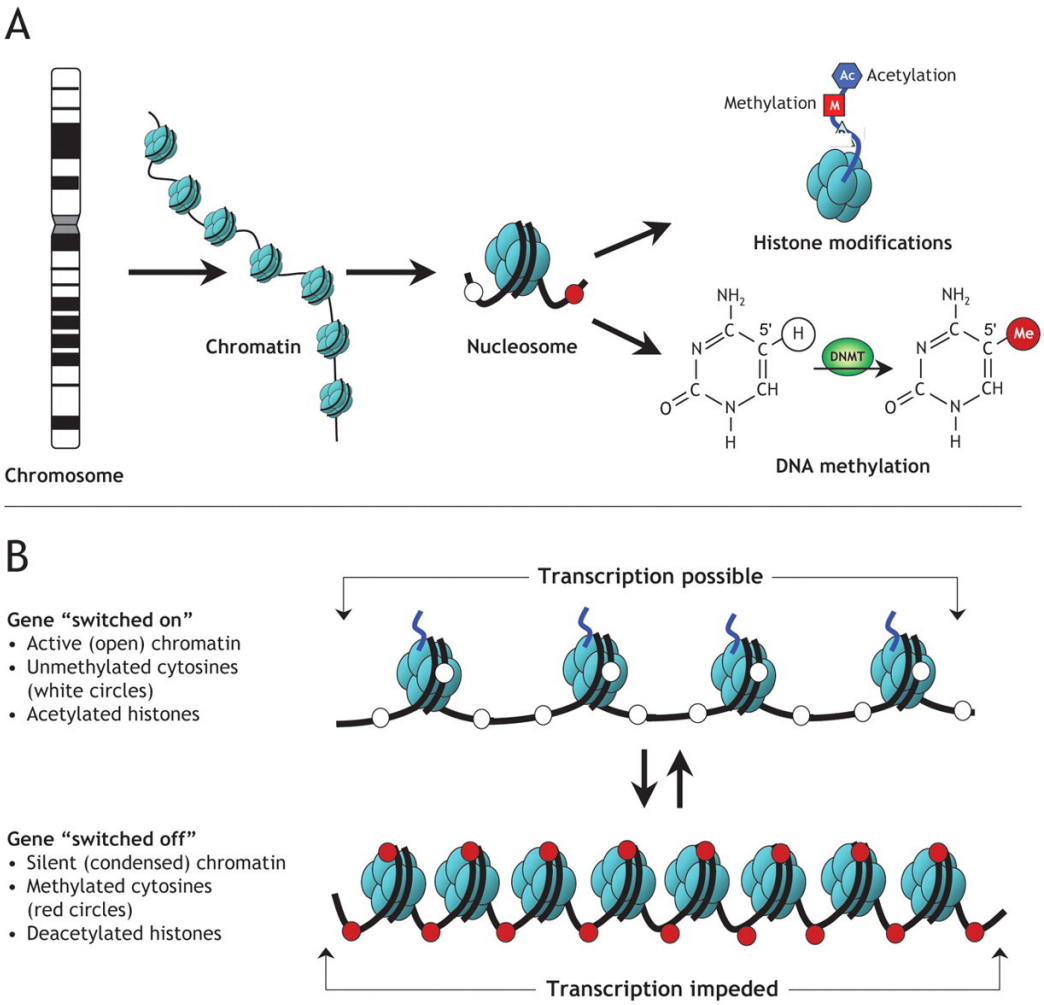

Figure 3: Chromosomes are composed of smaller subunits called nucleosomes, composed of a histone and a length of DNA. Histone modifications such as methylation and acetylation, and DNA methylation are two forms of epigenetic marks. These marks change the conformation of chromatin to open or closed, and permit or repress gene transcription respectively. Image taken from [220], with permission from the publisher.

2.2.4. **DNA Methylation, Gene Expression, and Pain**

Chiechio et al. 2009 conducted one of the first investigations of epigenetic mechanisms and chronic pain to find that HDAC inhibitors could produce analgesia in a mouse model of chronic inflammatory pain [221]. Since then, a number of human and animal studies have deepened our understanding and revealed the widespread contribution of DNA methylation and epigenetics to chronic pain throughout the body.

2.2.4.1. Human Studies

In human studies, measures of genome wide and gene specific DNA methylation are generally derived from circulating whole blood. Human studies have often focused on correlating single pain-related gene methylation to levels of pain sensitivity. TRPA1 receptor methylation has been studied in detail, with an inverse correlation to heat and mechanical pain thresholds in healthy individuals [222, 223]. Accordingly, TRPA1 gene expression inversely correlated with TRPA1 promoter methylation and positively correlated with heat pain threshold [222]. This relationship is maintained in chronic pain patients, with increased TRPA1 methylation associated with larger pain ratings in neuropathic pain and Crohn's patients [224-226]. μ-opioid receptor OPRM1 promoter methylation is positively correlated with reports of pre-operative pain and the probability of developing chronic post-surgical pain in adolescents [227]. Increased OPRM1 methylation also correlated with increased clinical pain in opiate-treated patients. It is unclear if increased OPRM1 methylation may be a result of opiate treatment rather than directly related with chronic pain [228]. Decreased BDNF methylation in exon IX,

correlating with elevated serum BDNF, has also been found to predict widespread hyperalgesia in fibromyalgia patients [229].

Genome-wide studies of human pain conditions have revealed the breadth of DNA methylation changes in response to chronic pain. In a study comparing complex regional pain syndrome (CRPS) and non-CRPS neuropathic pain patients, 48 differentially methylated CpG sites were identified and were enriched in immune domains [230]. 41 out of the 48 CpG positions were hypomethylated. In fibromyalgia patients, 1610 differentially methylated positions were identified compared to healthy controls, again with 69% of positions showing hypomethylation. The 960 genes correlated with these positions were enriched for MAPK signalling, regulation of the actin cytoskeleton, and focal adhesions [231]. Finally, in a study of 1708 twins, 24 differentially methylated positions were estimated to explain 6% of the variance in chronic widespread musculoskeletal pain. These differentially methylated positions were enriched for gene ontology terms related to nervous system activity and development [232]. These studies clearly demonstrate a strong relationship and response between DNA methylation and chronic pain, where changes in promoter methylation lead to changes in pain rating and in potential pain relevant mechanisms.

2.2.4.2. Animal Studies

Animal studies allow for the direct sampling of tissues of interest as well as a greater control over chronic pain presentation and paradigm. In rodent prefrontal cortex, chronic neuropathic pain is associated with widespread changes in DNA methylation. At six months post-onset of neuropathic pain, two studies have found global PFC DNA

methylation decreased and correlated with mechanical and cold sensitivity [233, 234]. The PFC methylation response nine months after neuropathic pain onset was analysed in detail and over 10000 differentially methylated promoters were identified at a false discovery rate < 0.1. These differentially methylated promoters were associated with long-term potentiation, neuritogenesis, DNA binding, and cell death [200].

DRG and spinal cord also undergo widespread differential methylation at multiple time points after onset of neuropathic pain. One day after neuropathic pain onset in DRG, over 8000 differentially methylated CpGs in promoters, introns, and exons were identified, over 80% were hypermethylated, and with axon guidance as the most significantly enriched function. Follow up RNA-seq analysis showed some correlation between promoter or gene body methylation status and mRNA expression, however the relationship is inconsistent [235]. The observed hypermethylation in DRG early after onset of neuropathic pain has been replicated, however at three weeks after onset, DRG differential methylation shifts towards hypomethylation. At this time point, the dorsal horn of the spinal cord and prefrontal cortex are skewed towards hypermethylation [236]. The dynamism of DNA methylation response to chronic pain highlights the need to track methylation changes across multiple phases and time points of chronic pain development.

A number of studies have also investigated interventions targeting DNA methylation and methylation mechanisms. Increased DNA methylation and MeCP2 binding in spinal cord two weeks after neuropathic pain onset was treated with intrathecal 5-azacytidine, a DNMT inhibitor. 5-azacytidine administration reduced global DNA methylation in the spinal cord and attenuated measures of pain sensitivity [237].

Meanwhile, chronic systemic SAM treatment increased PFC DNA methylation and counteracted the global PFC DNA methylation decrease observed six months after injury while also attenuating pain sensitivity [234]. These two studies demonstrate that interventions targeting DNA methylation must understand the direction of aberrant differential methylation to be effective. Non-pharmacological interventions have also been investigated and found to be effective. The global PFC DNA methylation decrease observed six months after nerve injury can be reversed and pain behaviour attenuated if animals are provided environmental enrichment three months after pain onset [233].

2.3. Rationale

Chronic pain is a prevalent and costly disease that has limited therapeutic options and induces widespread functional and anatomical changes in pain transduction systems throughout the body. DNA methylation, as a dynamic and environmentally responsive mechanism of regulating gene expression, has great potential to help researchers understand how chronic pain develops and is maintained. At the start of this thesis, the relationship between chronic pain and DNA methylation was only beginning to be understood, and subsequent work has only underscored this potential. By examining and tracking how chronic pain affects DNA methylation in the PFC, we may better identify and understand its underlying mechanisms. Beyond improving our understanding of chronic pain development and maintenance, DNA methylation can also help us observe the reaction of the PFC to therapeutic interventions. As a stable mark of changes in gene

expression, we can understand why and how certain interventions mediate their effects and attempt to identify ways to make them more effective.

2.4. Hypothesis

The prefrontal cortex undergoes dynamic DNA methylation responses as chronic pain begins and develops over time. Pharmacological and non-pharmacological interventions that reduce pain sensitivity will counteract or reverse these methylation responses.

2.5. Specific Aims

1) Track and observe PFC DNA methylation in response to induced neuropathic pain for up to 12 months post-injury
2) After chronic pain has developed, determine the PFC DNA methylation response to a pharmacological intervention
3) After chronic pain has developed, determine the PFC DNA methylation response to a non-pharmacological intervention

Chapter 2: Timecourse of DNA Methylation Response Across Chronic Pain

3.1. Preface

The development and progression of chronic pain is associated with a number of functional and structural changes in PFC grey matter. Changes in neuronal architecture, cortical excitability, and loss of grey matter have all been noted from the onset of chronic pain to months later in the chronic pain time course. Widespread changes in the PFC transcriptome have also been noted after the onset of chronic pain. DNA methylation has been proposed as a candidate mechanism to mediate and regulate these changes, and indeed a number of studies have explored changes in PFC DNA methylation in response to chronic pain. However, previous studies focused on a single time point and did not track the full time course of chronic pain development and progression. Examining PFC DNA methylation across the time course of chronic pain development will further our understanding of how DNA methylation responds to chronic pain, and identify functional domains and mechanisms affected by DNA methylation.

In this study we hypothesized that as chronic pain develops and progresses over time, the PFC will undergo a number of changes in DNA methylation. We characterized PFC DNA methylation at one day, two weeks, six months, and one year after spared nerve injury.

Abstract:

Chronic pain is associated with persistent structural and functional changes throughout the neuroaxis, including in the prefrontal cortex (PFC). The PFC is important in the integration of sensory, cognitive and emotional information and in conditioned pain modulation. We previously reported wide-spread epigenetic reprogramming in the PFC many months following nerve injury in rodents. Epigenetic modifications, including DNA methylation, can drive changes in gene expression without modifying DNA sequences. To date, little is known about epigenetic dysregulation at the onset of acute pain or how it progresses as pain transitions from acute to chronic. We hypothesize that acute pain following injury results in rapid and persistent epigenetic remodelling in the PFC that evolves as pain becomes chronic. We further propose that understanding epigenetic remodelling will provide insights into the mechanisms driving pain-related changes in the brain. Epigenome-wide analysis was performed in the mouse PFC 1 day, 2 weeks, 6 months, and 1 year following peripheral injury using the spared nerve injury (SNI) in mice. SNI resulted in rapid and persistent changes in DNA methylation, with robust differential methylation observed between SNI and sham-operated control mice at all time points. Hundreds of differentially methylated genes were identified, including many with known function in pain. Pathway analysis revealed enrichment in genes related to stimulus response at early time points, immune function at later time points and actin and cytoskeletal regulation throughout the time course. Given these results, importance of pain time course as a factor is emphasized for both pain research and treatment.

1. Introduction

Chronic pain is a global challenge, affecting between 10-20% of adults and costing billions each year in patient care and lost productivity [1, 2, 4]. Chronic pain is modulated by a complex mix of biological, psychological and social factors. At the molecular level, hundreds of genes become differentially expressed in chronic pain conditions [22, 200, 238-240]. Understanding chronic pain is further complicated by time-dependent recruitment of mechanisms and pathways mediating the transition from acute to chronic pain [241, 242]. Improved understanding of pathological gene dysregulation from acute to chronic pain is desperately needed to prevent the development of prolonged, intractable pain.

Epigenetic mechanisms allow for malleable and reversible gene regulation without modification of DNA sequences. DNA methylation is an epigenetic regulator of gene expression wherein a methyl group is added to cytosine DNA nucleotides. When methylation occurs in gene promoter regions, the gene is typically repressed via hindrance of transcription factor binding, recruitment of methyl binding proteins, and chromatin remodeling, ultimately preventing RNA polymerase-mediated transcription [243, 244].

DNA methylation is environmentally sensitive, with methylation profiles changing in response to addiction, early life stress, and neurodegenerative disease [198, 245, 246]. Chronic pain is also associated with changes in DNA methylation in both humans and animal models across many tissues including the prefrontal cortex (PFC), dorsal root ganglia, and spinal cord [22, 200, 235, 236]. DNA promoter methylation at specific genes

can be linked to the degree of mechanical hypersensitivity [200], and chronic treatment with methyl donor S-adenosylmethionine increased global DNA methylation in the PFC and attenuated mechanical hypersensitivity [234]. Investigation of DNA methylation's role in chronic pain advances our understanding of pain progression and may reveal potential therapeutic avenues.

Among the structures involved in chronic pain, the PFC is crucial as an integrator of ascending sensory information, cognitive and emotional responses, and descending inhibitory control [37, 247, 248]. In human patients and animal subjects, long-term pain results in a persistent functional and anatomical reorganization of the PFC [15, 20, 82, 249], with patients showing more PFC activation than healthy controls [14, 48]. Chronic pain patients are commonly comorbid for depressive and anxiety disorders [250] that are heavily correlated with PFC abnormal functioning [251, 252]. As a central mediator in the pain pathway, therapeutic mechanisms targeting PFC may have efficacy across different pain disorders and simultaneously address associated cognitive and emotional comorbidities.

Previous work has shown extensive changes in DNA methylation and dynamic structural and functional reorganization in the PFC to be associated with chronic pain. To track epigenetic reprogramming in the PFC in acute and chronic pain, we captured the pattern of genome-wide DNA methylation across time from 1 day to 1 year following peripheral nerve injury in mice. Our analysis revealed a dynamic pattern of DNA methylation across the time course, implicating hundreds of differentially methylated genes at each time point. Subsequent analysis revealed time point-specific changes that

reveal potential underlying mechanisms. Our data show that epigenetic reprogramming occurs early during the transition from acute to chronic pain and is consistent with a potential causal role.

2. Materials and Methods

2.1 Animals

78 male CD-1 mice (Charles River Laboratories, St-Constant, QC, Canada) mice were used in this study. Animals were received at 6-8 weeks of age and housed 3-4 per cage on a 12h light/dark cycle in a temperature controlled room in ventilated polycarbonate cages (Allentown, Allentown, NJ) with corncob bedding (7097, Teklad Corncob Bedding, Envigo, UK) and cotton nesting squares for enrichment. Mice were given access to food (2092X Global Soy Protein-Free Extruded Rodent Diet, Irradiated) and water *ad libitum*. Animals were habituated to the housing conditions for at least one week prior to any experimental interventions.

Animals designated for DNA methylation analysis were randomly assigned to receive either the spared nerve injury (SNI) model of neuropathic pain or sham surgery control and the model was allowed to develop for one day (D1), two weeks (W2), six months (M6), or one year (1Yr) post-injury. Final numbers per group (Sham/SNI) – D1:4/4; W2:6/6; M6:6/6; 1Yr:4/6; 42 animals in total.

Animals designated for immunohistochemistry were randomly assigned to either SNI or sham surgery and allowed to progress to two weeks or six months post-injury. Final numbers per group (Sham/SNI) – W2:10/8; M6:10/8; 36 animals in total.

All experiments were approved by the Animal Care Committee at McGill University, and conformed to the ethical guidelines of the Canadian Council on Animal Care and the guidelines of the Committee for Research and Ethical Issues of the International Association for the Study of Pain [253].

2.2 Induction of spared nerve injury

Nerve injury was induced using the Spared Nerve Injury model of neuropathic pain, as adapted for mice [254, 255] at 10 to 12 weeks of age. Under deep isoflurane anesthesia, an incision was made on the medial surface of the thigh, exposing the three branches of the sciatic nerve. SNI surgery consisted of ligation and transection of the left tibial and common peroneal branches of the sciatic nerve, while sparing the sural nerve. The tibial and common peroneal branches were tightly ligated with 6:0 silk (Ethicon) and sectioned distal to the ligation. Sham surgery consisted of exposing the nerve without damaging it.

2.3 Behavioural assessment of mechanical sensitivity

After a habituation period of 1 hour to the testing environment of Plexiglas boxes placed on a wire mesh grid, von Frey filaments (Stoelting Co, Wood Dale, IL) were applied to the plantar surface of the hind paw to the point of bending for 3 seconds or until withdrawal. Mechanical sensitivity was determined as the 50% withdrawal threshold

using the up-down method [256]. The stimulus intensity ranged from 0.04 to 4.0 g, corresponding to filament numbers 2.44 to 4.56. Testers were blind to the condition of the animal.

2.4 Immunofluorescent histochemistry

Animals were deeply anesthetized with an intraperitoneal injection of ketamine (100 mg/kg), xylazine (10 mg/kg), and acepromazine (3 mg/kg). Animals were perfused with 100 mL vascular rinse (0.2M phosphate buffer with sodium nitrate), followed by 200 mL Lana's fixative (4% paraformaldehyde, 14% saturated picric acid, 0.16M phosphate buffer, pH 6.9), and then 100 mL 10% sucrose solution in phosphate buffered saline. Tissue was cryoprotected in 10% sucrose solution at 4°C for three days, and then coronally divided at Bregma into forebrain and hindbrain sections. Brain tissue was coronally sectioned at 14µm on a cryostat (Leica), and PFC sections, defined as +1.54 mm to +1.98 mm from Bregma, were collected. Prelimbic and infralimbic areas were defined according to Paxinos and Franklin [257].

Tissue was incubated with blocking buffer (1% Normal Donkey Serum, 1% Bovine Serum Albumin, 0.3% Triton X-100, 0.01% Sodium Azide) for 1 hour before primary antibody incubation overnight at 4°C. Tissue sections were either singly stained with rabbit anti-NeuN (1:1000, Abcam, Ab177487), or double stained with mouse anti-NeuN (1:1000, Millipore, MAB377) and either rabbit anti-GFAP (1:1000, Neomarkers, RB087AO) or rabbit anti-Iba1 (1:1000, Wako, 019-19741). Rabbit anti-NeuN was used to quantify neuronal cell counts while mouse anti-NeuN was used as a counter stain to define cortical layers in double-stained sections. Secondary antibodies (donkey anti-rabbit Alexa 594

(1:200, Jackson ImmunoResearch, 711-585-152) and donkey anti-mouse Alexa 488 (Jackson ImmunoResearch, 714-545-150) were incubated for 90 min at room temperature. Sections were counterstained with DAPI (1:50000, Sigma, D9542) and coverslipped with AquaPolymount (18606, PolySciences).

2.5 Immunohistochemistry quantification

FIJI [258] and manual cell counting were used to quantify the number of total cells, neurons, astrocytes, and microglia in prelimbic and infralimbic brain areas. DAPI was used as a marker of total cell population, NeuN-immunoreactivity (-ir) defined neuronal populations, GFAP-ir defined astrocyte populations, and Iba1-ir defined microglial populations. NeuN staining was also used to separately designate layer I, superficial (layers II-III) and deep (layer V) cortical layers to aid the placement of three regions-of-interest (ROIs) per layer. Cell quantification was based on colocalization of the cell type specific marker with DAPI, and cell counts were averaged across three ROIs per layer. The averaged ROI area per cortical layer: layer I: 6724 μm^2; superficial (layers II-III): 15790.14 μm^2, deep (layer V): 10526.76 μm^2. An overall cell count was calculated by adding the counts from all three layers. Total ROI area: 33040.9 μm^2. ROI sizes were identical between prelimbic and infralimbic areas.

2.6 Isolation of prefrontal cortex, DNA capture and bisulfite sequencing

Mouse PFC was dissected following isoflurane anesthesia and decapitation. PFC was defined as a region with an anterior boundary of the frontal pole, approximately +3.00 Bregma, posterior boundary of +1.42 Bregma, lateral boundaries of +1 mm from midline, and a ventral boundary wherein the olfactory bulb, caudate putamen, and areas below

the rhinal fissure and lateral ventricles were all removed [257]. This defined area isolates the prelimbic, orbital, and infralimbic cortices corresponding to the mouse medial PFC. Once dissected, tissue was homogenized and genomic DNA was extracted using the Qiagen DNeasy Blood and Tissue kit and protocol.

Genome-wide methylation analysis was performed using the Roche SeqCap Epi Developer M Enrichment system on bisulfite-treated DNA (Roche Nimblegen; WI, USA), with custom designed primers targeting promoter and enhancer regions of the genome. Probe design was based on the mm9 reference genome and associated H3K4me1 and H3K4me3 binding (probe BED file available in **Supplemental Table 1**). Briefly, 1 μg of genomic DNA per sample was fragmented into 200bp lengths, and adapter and index sequences were ligated to each end of the fragment according to the KAPA Library Preparation Kit protocol. Sample DNA was then bisulfite converted following the EZ DNA Methylation-Lightning Kit (Zymo Research; CA, USA). Sample DNA was then PCR amplified, hybridized with custom capture probes, and PCR amplified again in accordance with Roche SeqCap Epi system protocols [259]. Sample captured bisulfite-converted DNA sequencing was performed by Genome Quebec on the Illumina HiSeq 2500 following Illumina guidelines. Paired-end sequencing reads of 125bp in length were generated.

2.7 DNA methylation pre-processing

Capture sequencing data was pre-processed using the McGill University Genome Quebec Innovation Centre GenPipes Methyl-Seq Pipeline [260]. The pipeline proceeds through Trimmomatic, Bismark Align, Picard Deduplication, and Bismark Methylation Call

[261, 262]. Baseline pipeline parameters were set as a minimum sequence quality of PHRED score > 30, alignment reference genome was mm10 (GRCm38), and minimum read coverage per base was set at 10 reads. A detailed outline of the Methyl-Seq pipeline steps and process can be found at https://bitbucket.org/mugqic/genpipes. Before analysis, collected sequence data was filtered to remove a blacklist of regions identified to have anomalous, unstructured, and high signal/read counts in next gen sequencing [263]. The blacklist used was specific for mm10 and the BED file can be found in **Supplemental Table 2.**

2.8 Differential methylation analysis

Generalized linear model analysis was used to compare Sham to SNI methylation values at each time point. Differential methylation analysis was performed using R and the edgeR package [264]. Samples were normalized to library size, where library size was set to be the average of the total read counts for methylated and unmethylated CpGs. For a CpG site to pass through to analysis, it was required to be sequenced at a depth of at least 10 reads in each sample within a time point.

At each time point, CpGs were defined as being differentially methylated if the false discovery rate (FDR) was less than < 0.1 and a difference in methylation between Sham and SNI of > 5%. While the selection of an FDR threshold of 0.1 carries greater risk of type I error than the more typical threshold of 0.05, it is preferable for the exploratory purposes of this study. Differential methylation between Sham and SNI was determined by calculating the M-Value ($\log_2$ of the ratio (methylated cytosines / unmethylated cytosines)) of each CpG site in Sham and SNI, and then detecting statistically significant

differences. The methylation percentage (percentage of (methylated cytosines / total cytosines)) at each site was also calculated. Differentially methylated samples were further divided into hypermethylated CpGs or hypomethylated CpGs with the Sham CpG methylation percentage acting as the reference point. If the SNI CpG methylation is 5% or larger than the Sham, the CpG position is considered to be hypermethylated. If the SNI CpG methylation is reduced by -5% or more compared to Sham, the CpG position is considered to be hypomethylated.

CpGs were annotated to their associated genes and genomic regions using the topTags function of edgeR [264] and annotatePeaks function of the ChIPseeker [265] R packages, using a TxDb object created from the Gencode “mmusculus_gene_ensembl” Biomart database. Each CpG position was annotated and tracked individually throughout the analysis. For homology conversion, gene symbols from non-mouse species were converted to known mouse homologs based on the Mouse Genome Database (MGD) – Vertebrate Homology, Mouse Genome Informatics, The Jackson Laboratory, Bar Harbor, Maine [266].

The data discussed in this publication have been deposited in NCBI's Gene Expression Omnibus [267] and are accessible through GEO Series accession number GSE146215.

2.9 Statistical analysis

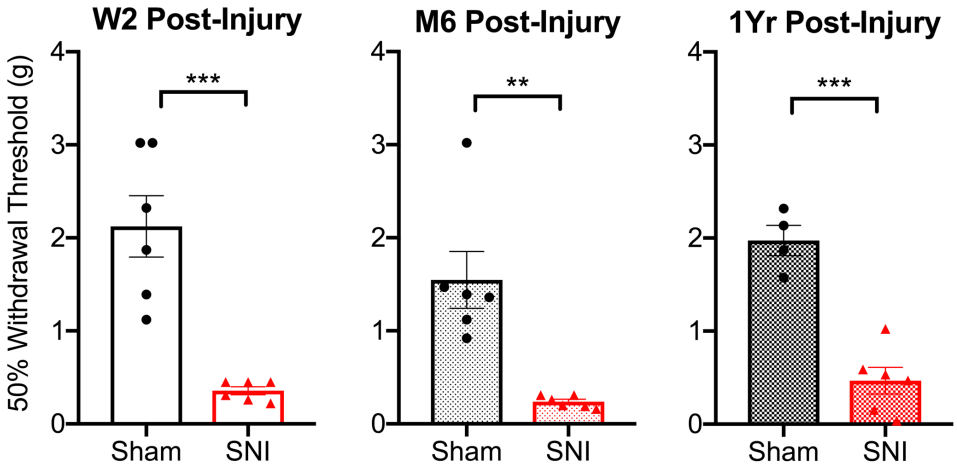
Two-tailed Student’s t-test was used for group differences between Sham and SNI in the von Frey mechanical sensitivity behavioural assay (Figure 1). A two-tailed Welch’s

t-test was used to test for differences in cell type counts between Sham and SNI (Figure 2). Differences between the magnitude of differential methylation across time points was identified using a Welch's ANOVA followed by Games-Howell's post-hoc test for multiple comparisons (Figure 3). Pairwise comparisons of CpG positions at each time point utilized a negative binomial generalized linear model to fit the data and differential methylation was determined utilizing the likelihood ratio test. Analyses were corrected for multiple comparisons using the Benjamini-Hochberg FDR (Figure 4). Post-hoc supervised hierarchical clustering analysis was performed using Ward's method and 1 – Pearson correlation as the distance metric (Figure 5-8A). Hypergeometric test was used to test for significant enrichment of pain-related and other experimentally identified genes.

2.10 Gene ontology analysis

Differentially methylated genes identified at each time point were submitted to Metascape [268], a web-based Gene Ontology tool. The CORUM, the Reactome Gene Sets, the KEGG Pathway, Functional Set and Structural Complex, and the GO Biological Processes, Cellular Component and Molecular Function databases were selected as ontology databases. An ontology was considered enriched at a p-value < 0.05, minimum gene count of 3, and a minimum enrichment factor > 1.5. At each time point, 15 representative gene ontologies were selected on the basis of p-value, number of differentially methylated genes within the ontology, and being a parent term to other identified ontologies. At most, only 66% of differentially methylated genes within a representative ontology are identical to the differentially methylated genes identified in any other representative ontology.

3. Results



3.1 Spared nerve injury results in long-term neuropathic pain but has no impact on the proportions of neurons, astrocytes and microglia in the prefrontal cortex

Before performing bisulfite sequencing, we validated the presence of long-term neuropathic pain **(Figure 1).** To control for non-epigenetic mechanisms that might drive differential DNA methylation, we verified that the proportions of neurons, astrocytes and microglia do not differ between Sham and SNI animals at W2 and M6. As each cell type has its own DNA methylation profile, differential methylation between Sham and SNI animals could result from the gain or loss of specific cell populations.

3.1.1 Behavioural signs of neuropathic pain persist up to one year following spared nerve injury

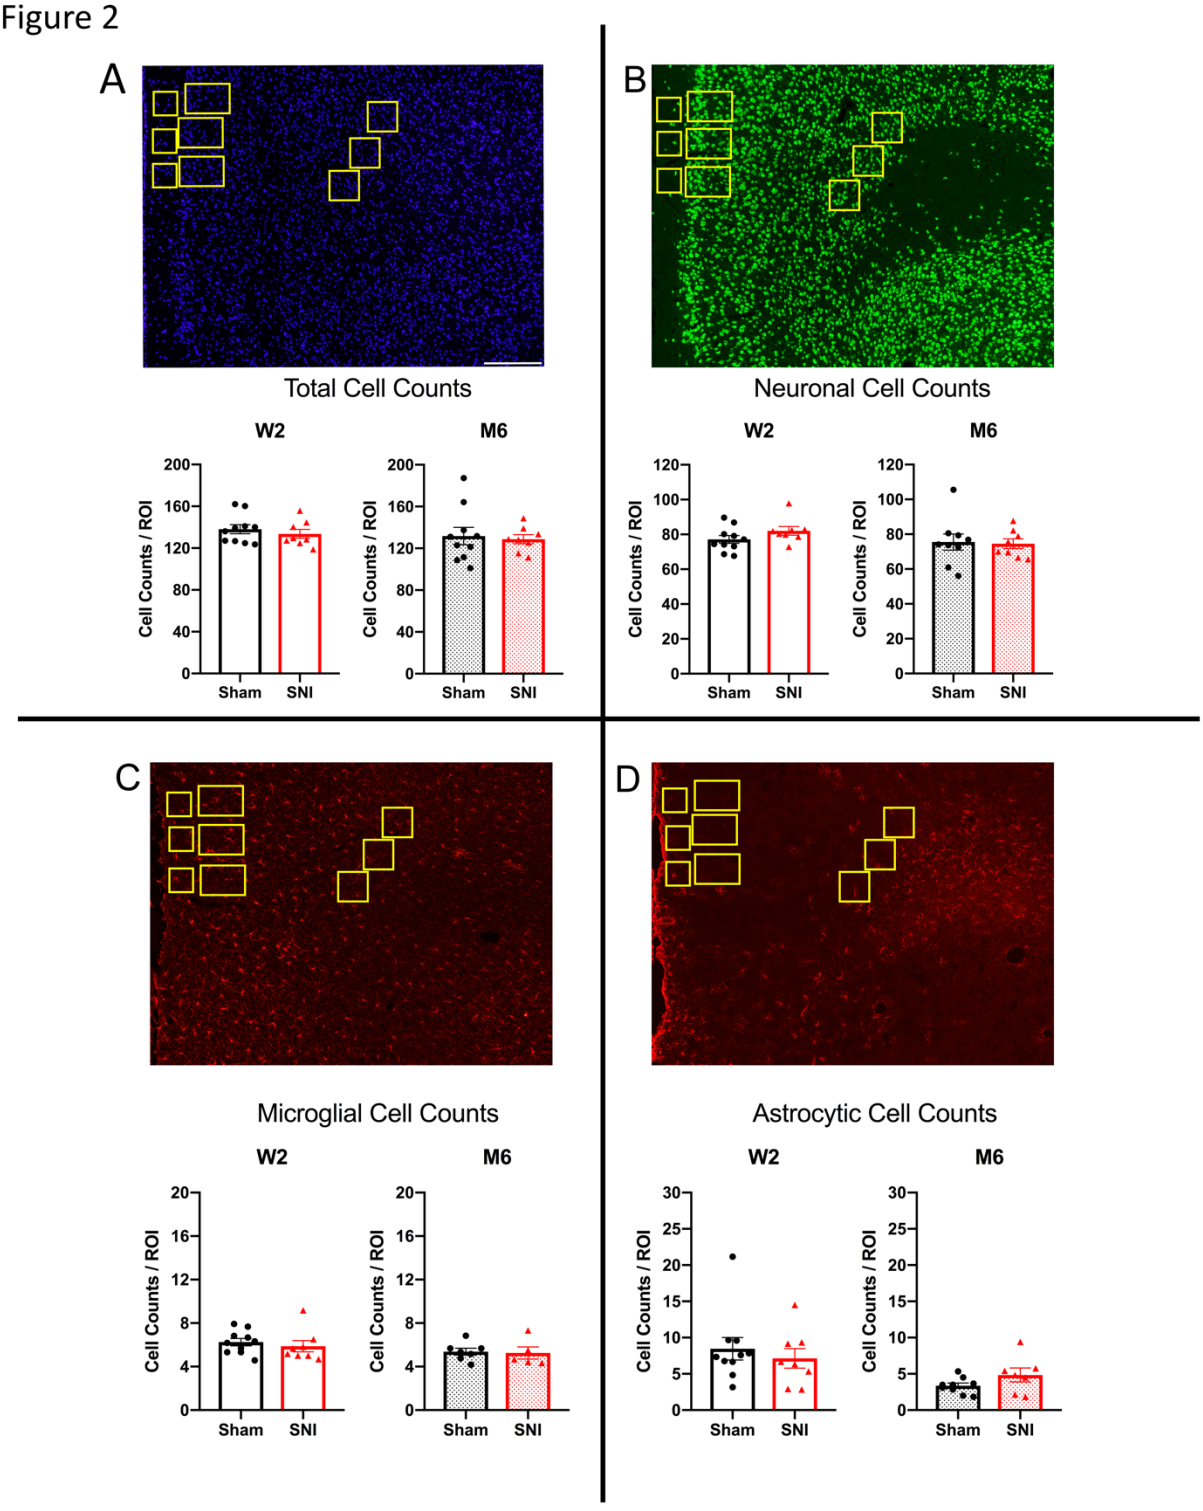
To confirm long-term neuropathic pain, mechanical sensitivity was assessed using the von Frey assay at 2 weeks, 6 months, and 1 year following SNI. SNI animals were more sensitive to mechanical stimuli applied to the plantar surface of the hindpaw ipsilateral to the injury at all time points when compared to their respective sham animals (Two-tailed Student's t-test. *W2*: $t_{10} = 5.3$, $p = 0.0003$; *M6*: $t_{10} = 4.2$, $p = 0.002$; *1Yr:* $t_8 = 6.8$, $p = 0.0001$) (**Figure 1**). The reduction in 50% withdrawal thresholds in SNI animals indicates the presence of a persistent and stable mechanical hypersensitivity for up to 1 year.

Figure 1

[**Figure 1 – Mechanical hypersensitivity persists for up to 1 year following spared nerve injury (SNI)**. Nerve injured mice were hypersensitive to mechanical stimuli compared to sham mice at two weeks (W2), six months (M6), and one year (1Yr) post-SNI. Bars represent mean ± SEM withdrawal threshold expressed in grams. *Two-tailed Student's t-test,** = $p < 0.01$; *** = $p < 0.001$, n = 4-6/group.*]

3.1.2 Spared nerve injury has no impact on the proportions of neurons, astrocytes and microglia in the prefrontal cortex

The neuronal, astrocytic, and microglial cell populations were quantified in the PFC by immunohistochemistry to quantify SNI-related changes 2 weeks and 6 months following surgery. Overall cell counts were calculated independently in prelimbic and infralimbic cortical areas as well as at three cortical depths: layer I, superficial layers (layer



II-III), and deep layers (layer V). No significant differences were detected between SNI and Sham for any cell types in either the prelimbic (Two-tailed Welch's t-test. **DAPI** *W2***:** $t_{15.80} = 0.7$ p = 0.48; *M6***:** $t_{13.21} = 0.3$, p = 0.75. **NeuN** *W2***:** $t_{15.16} = 1.5$, p = 0.16; *M6***:** $t_{12.96} = 0.2$, p = 0.86. **GFAP** *W2***:** $t_{16} = 0.6$, p = 0.53; *M6***:** $t_{7.80} = 1.4$, p = 0.19. **Iba1** *W2:* $t_{12.48} = 0.6$, p = 0.55; *M6:* $t_{6.51} = 0.2$, p = 0.86) **(Figure 2)** or infralimbic **(Supplemental Figure 1)** regions at either time point.

3.2 Spared nerve injury produces rapid, large and persistent changes in DNA methylation in the prefrontal cortex

Differentially methylated (DM) CpG sites were identified by bisulfite capture sequencing by comparing SNI vs. Sham. In this study only DM CpGs that were annotated to promoter regions were selected for analysis due to the inverse relationship between CpG DNA methylation and gene expression (in general, less methylation = increased gene expression; more methylation = reduced gene expression [269]).

Table 1 shows the number of DM CpG sites after adjusting for multiple comparisons. At each of the four time points evaluated, at least 350 DM CpGs were identified at an FDR adjusted p-value threshold of 0.1. Increasingly stringent thresholds still identify a large number of differentially methylated positions. Notably, a subpopulation of DM CpGs remain significant at an FDR adjusted p-value < $1x10^{-7}$, representing a substantial and consistent change between Sham and SNI and strong effect of injury.

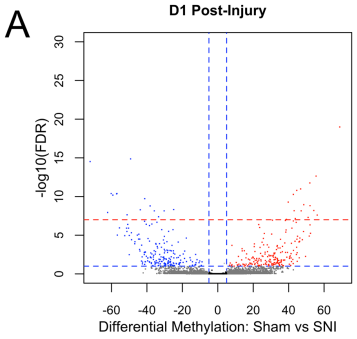
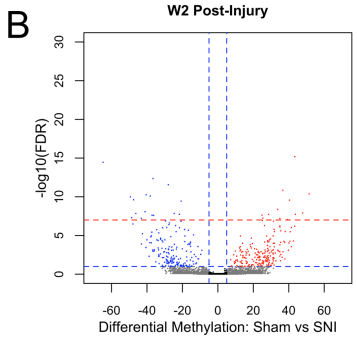
of 0.1. *Likelihood ratio test with Benjamini-Hochberg false discovery rate correction for multiple comparisons.*]

The magnitude of differential methylation at each time point of all DM CpGs is displayed in **Figure 3.** The average magnitude of differential methylation between Sham and SNI is approximately 25-30% at all time points. This is a robust shift in methylation state for most DM CpG positions and is on par with that observed in the brain for major depressive disorder [270].

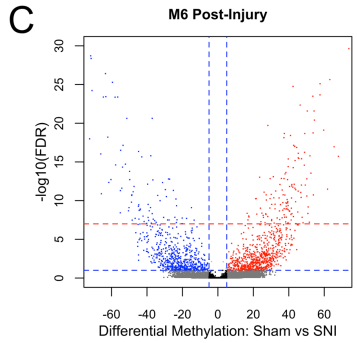
The effect of peripheral injury on PFC methylation is immediate, with the largest degree of differential methylation between Sham and SNI detected at D1 post-injury, indicating a rapid response to injury. D1 had a significantly higher average methylation change between Sham and SNI than the other time points (Welch's ANOVA followed by Games-Howell's post-hoc test: D1 vs. W2/M6/1Yr, $p < 0.0001$), with 75% of CpGs having a greater than 25% change in methylation, and 25% of CpGs having a change larger than 38%. The W2 and 1Yr time points were the most tightly clustered, with 50% of DM CpGs within 6-7% of their mean differential methylation. Despite having the lowest average percent differential methylation, the M6 time point had a large subpopulation skewed towards high levels of methylation change. These highly DM CpGs may play an important role in the transition from subacute to chronic pain.

Figure 3

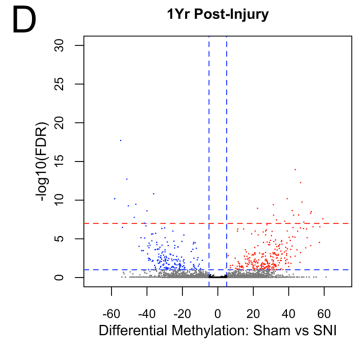




[**Figure 3 – Magnitude of differential methylation following spared nerve injury (SNI)** Differential methylation is expressed in terms of absolute percentage of change between Sham and SNI at 1 day (D1), 2 weeks (W2), 6 months (M6) and 1 year (1Yr) post-surgery. Each dot is an individual CpG. *Welch's ANOVA with Games-Howell's test for multiple comparisons.. **p<0.01, ****p< 0.0001. n = 4-8/group.*]



The effect of injury upon PFC methylation is also persistent, with differential methylation observed throughout the time course. Within each time point there were no significant differences in the number of hyper- vs. hypo-methylated CpGs. (**Figure 4A-E**). This balance suggests locus-specific methylation targeting as opposed to a global increase or decrease in DNA methylation.



To explore how patterns of methylation evolve at individual CpGs across time, we grouped all CpGs that were differentially methylated at a minimum of 3 out of the 4 time points **(Figure 4F).** While the direction of differential methylation is largely consistent across time for some CpGs, others display dynamic patterns as a function of chronicity. For example, the actin cytoskeleton remodeling gene, WAS/WASL interacting protein family member 2 (*Wipf2*), is consistently hypomethylated, while the cell adhesion gene Contactin 1 (*Cntn1*), fluctuates between hypo- and hypermethylation across the entire time course. Taken together, the DNA methylation response to peripheral nerve injury is rapid, large, dynamic, and persists throughout the entire time-course.

Values are displayed as differential methylation. ** = FDR adjusted p-value < 0.1.*]

3.3 Spared nerve injury results in time point-specific differential methylation of individual genes and functional pathways in the prefrontal cortex.

To determine the functional impact of these substantial shifts in the PFC methylation landscape, we performed gene annotation and downstream analyses to identify associated genes and gene ontologies.

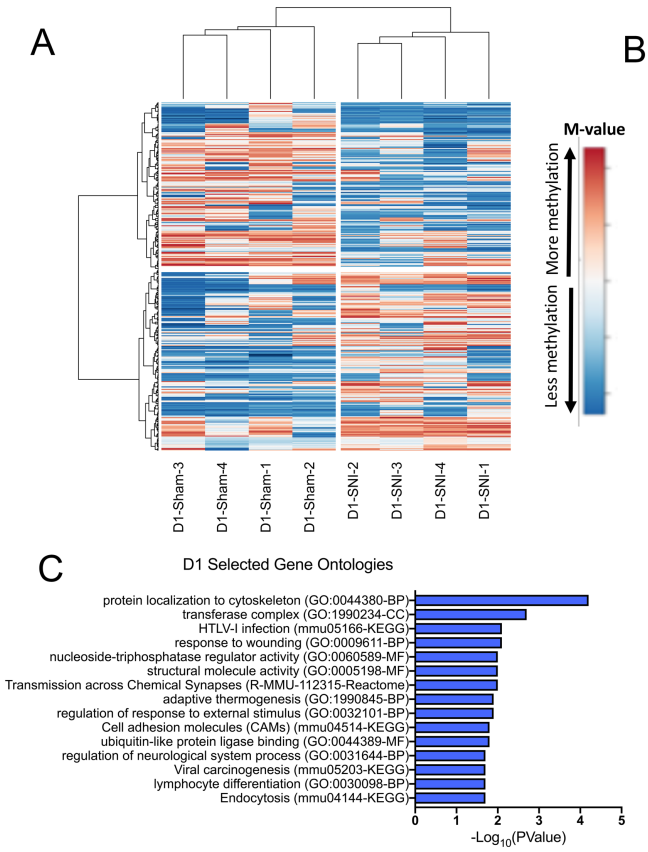
DM CpGs were annotated to their corresponding gene based on the mm10 reference genome. We found that 61.3% of annotated CpGs were the only DM CpG annotated to a gene promoter within a time point. In contrast, 35.5% of annotated CpGs were part of clusters of 2-6 DM CpGs annotated to a promoter region and the remaining 3.3% of CpGs existed within clusters of 7+ CpGs, corresponding to the promoters of 4 genes*: Organic Solute Carrier Partner 1 (Oscp1), Midline1 (Mid1), Toll-like receptor 6 (Tlr6) and 1110020A21Rik.*

Of the genes identified with multiple DM CpGs within a time point, the vast majority (88.5%) were either all hyper- or all hypo-methylated within that promoter, suggesting that the resulting dysregulated genes are likely to be either up- or down-regulated.

Supervised clustering was performed at each time point to visualize clusters of covarying DM CpGs and the characteristic methylation profile of Sham and SNI animals (**Figure 5A-8A**).

To identify the most differentially methylated genes at each time point, a promoter region index was determined by multiplying the adjusted p-value of each CpG by the number of CpGs within the promoter region. The top 25 differentially methylated genes at each time point as determined by promoter region index can be viewed in **Figures 5B-8B**, listing the average adjusted p-value, average differential methylation, number of DM CpGs identified within the gene promoter, and number of hyper- or hypo-methylated DM CpGs. In cases with mixed differential methylation in the promoter, the average methylation for both hyper-methylated and hypo-methylated CpGs are shown separately.

Full lists displaying individual DM CpGs and their annotated genes are available in **Supplemental Table 3.**



To identify broader effects of differential gene methylation and therefore potential functional dysregulation, gene ontologies enriched for differentially methylated genes were also identified (**Figure 5C-8C**). The full list of enriched ontologies by time point can be observed in **Supplemental Table 4.**

3.3.1 One day post-injury

At D1, 396 DM CpGs identified 327 unique genes undergoing differential methylation in their promoter region. The top 25 differentially methylated genes were related to cell-cell interaction (*Ccdc85a, Cntn1*), cell structure (*Banf2, Cep63, Mid1*), and immune response (*Cystlr2, H2-Q4, Icos, Mapkbp1, Unc5cl*) (**Figure 5B)**. *Mapkbp1, H2-Q4, Icos*, *Unc5cl*, have involvement in TLR, NFκB, and TNF signaling pathways, with additional immune related genes *Acod1, Cd14, Itch, H2-K1, H2-M1, Mapkapk3, Mapkapk5,* and *Tnfrsf13c* also identified as differentially methylated at this time point. While not part of the top 25 differentially methylated genes, actin and cytoskeletal dynamics genes (*Acta2, Diaph1, Dvl1, Macf1, Wipf2*) are also observed.

Gene ontology analysis identified functional pathways enriched for differentially methylated genes involved in response to stimulus, cellular structure remodeling, and extracellular matrix formation **(Figure 5C)**.

ontology: minimum gene count of 3, p < 0.05, and a minimum enrichment of 1.5. n = 4 mice/group.]

3.3.2 Two weeks post-injury

At W2, 370 DM CpGs identified 311 unique genes undergoing differential methylation in their promoter region. The top 25 differentially methylated genes had involvement in actin processes (*Mical3*), cell surface molecules (*Gpc6, Prom1*), and immune regulation (*Btla, Ccl7*) (**Figure 6B**), In addition to the top 25, the W2 time point revealed genes involved in cellular structure and organization processes, such as actin and cytoskeleton (*Capza3, Epb41l1, Fhdc1, Myh2, Mprip, Shroom3, Tns1, Tns4, Wipf2)*, extracellular matrix (*Col4a1, Col6a4, Halpn3, Rpsa*) and cell-cell interactions (*Nectin2, Lgals4*). Also of interest is the differential methylation of *Ramp1,* which is crucial for the maturation and transport of CALCRL and its function as the CGRP receptor.

At W2, identified gene ontologies are involved with cellular structure remodeling, extracellular matrix, response to stimulus, and changes to internal cellular functioning (**Figure 6C**).

3.3.3 Six months post-injury

At M6, 1418 DM CpGs identified 1001 unique genes undergoing differential methylation in their promoter region. The top 25 differentially methylated genes were involved in E3 ubiquitination (*Mid1, Trim21, Trim30d*), and immune functioning (*Gdf15, Fam129c, Arhgef2*) (**Figure 7B**), In addition to the top 25, the M6 time point also displays a substantial number of immune genes across many different pathways (*Cd6, Ltbp1, Trem2;* TNF: *Traf3ip1, Traf6;* Interleukin: *Il12b, Il12rb1, Jak3;* TLR: *Lbp, Acod1, Myd88, Tlr6*). Actin regulation and formation is also affected, with numerous differentially methylated GTPases and guanine exchange factors (*Arhgap8, Arhgap15, Arhgap17, Arhgap33os, Arhgef2, Arhgef10l, Arhgef17, Arhgef19*).

At M6, the gene ontologies are related to immunological responses and systems, transcription factors, signaling cascades, and enzymatic processes (**Figure 7C**).

3.3.4 One year post-injury

At 1Yr, 435 DM CpGs identified 359 unique genes undergoing differential methylation in their promoter region. The top 25 differentially methylated genes are involved in actin regulation (*Mprip, Parva, Txnrd1*), histone methylation (*Smyd1*), and the acid sensing channel *Asic3* (**Figure 8B**)*,* In addition to the top 25, genes were identified that are involved with cell adhesion molecules (*Cldn13, Cldn15, Hapln3, Madcam1, Nectin2, Nfasc*) and extracellular matrix (*Col17a1, Lama3*).

At 1Yr, the top selected gene ontologies are related to cellular signaling, extracellular matrix formation, and cellular function regulation (**Figure 8C**).

3.4 Spared nerve injury results in function-specific responses across the time course

To identify trends in the functional responses to peripheral nerve injury across time, we overlapped all gene ontologies that were significantly enriched in differentially methylated genes at all time points. Overall, of the 775 enriched gene ontologies identified across all four time points, 658 gene ontologies were unique to one time point, 91 overlapped across two time points, 6 were found at three time points, and none were found to overlap across all four time points (**Figure 9A**). Displayed are the top 5 overlapping ontologies between time points, as determined by greatest averaged p-values and a minimum of 3 enriched genes at each time point in the ontology (**Figure 9B**). When identifying the overlapping gene ontologies at each time point, early time points D1 and W2 display ontologies more related to responding to external stimuli and damage, while later time points M6 and 1Yr display ontologies more related to adaptive immune response and T-cell mediated cytotoxicity. In all overlapping ontologies between time points, there is a strong contribution of actin and cytoskeleton related ontologies. These dysregulated pathways may contribute to functional and structural cortical remodeling previously reported in chronic pain conditions.

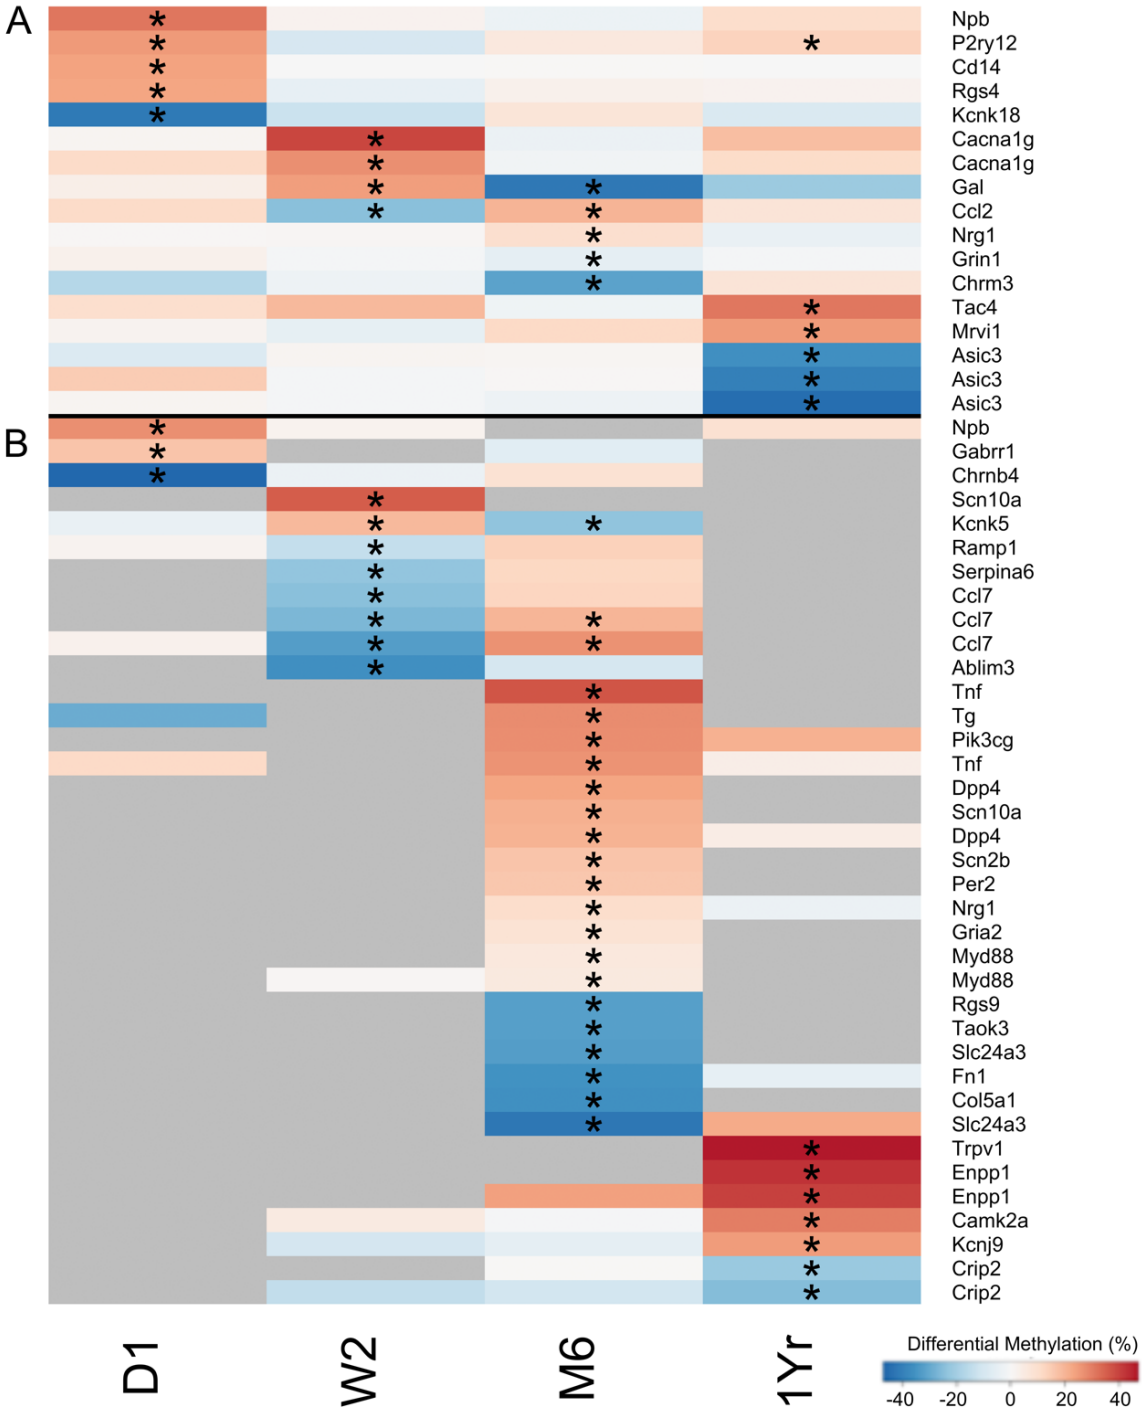
3.5 Pain-related genes show time point-specific patterns of differential methylation

To determine if any of the identified DM genes had been previously linked to pain, we cross-referenced with datasets of previously identified pain-related genes (**Figure 10**). Ultsch, Kringel [271] previously identified 535 human and mouse genes associated with pain. After conversion to mouse gene homologs, we identified 31 differentially methylated pain-related genes representing a significant enrichment (hypergeometric test, $p = 0.03$). The Human Pain Genes Database (HPGD) has identified 361 genes in humans wherein SNPs have been found to affect the sensation of pain [272]. 289 HPGD genes had known mouse homologs, of which 15 differentially methylated genes were found in our dataset, however was not significantly enriched (hypergeometric test, $p = 0.21$).



When tracking the differential methylation pattern of pain-related genes across the time course, most only show differential methylation at one time point. At D1, pain-related genes were involved in immune response (*Cd14*), and a number of ion channels (*Chrnb4, Gabrr1, Kcnk18*). At W2, pain-related genes were related to actin (*Ablim3*), immune regulation (*Ccl2, Ccl7*), and ion channels (*Cacna1g, Kcnk5, Scn10a*) At M6, identified pain-related genes are involved in immune responses (*Ccl2, Ccl7, Dpp4, Myd88, Pik3cg, Tnf*), cell-cycle regulation (*Taok3*), and ion channels and transport (*Chrm3, Kcnk5, Scn2b, Scn10a, Slc24a3*). At 1Yr, pain-related genes were involved in ion channels (*Asic3, Kcnj9,* Trpv1), peptide signaling (Tac4), and G-protein coupled receptor signaling (*P2ry12*).

For pain-related CpGs that were able to be captured at all time points, only three CpGs had differential methylation at more than one time point (*P2ry12, Gal,* and *Ccl2*) (**Figure 10A)**. Interestingly, galanin (*Gal)* and chemokine ligand 2 (*Ccl2)*, both show

reversals of their methylation state from W2 to M6. The methylation reversal of these two pain genes may indicate that the recruitment of pain-related processes may change across the time course, and genes have a temporal impact upon chronic pain development. While limited by a lack of data at all time points, a similar time point specific pattern of significant differential methylation was observed for CpGs that were not captured at all time points (**Figure 10B).** Therefore while a gene may be pain-related, its contribution to a pain phenotype may be restricted or limited in time.

We also cross-referenced our M6 experimental genes with two gene sets identified in our previous studies. Massart et al. 2016 examined rat PFC DNA methylation at 9 months post-SNI and identified 3981 genes that undergo differential methylation, with 3011 identified mouse homologs [200]. Our dataset was significantly enriched for genes identified in Massart et al. (hypergeometric test, $p = 0.02$) with 107 overlapping genes and 56 genes with consistent differential methylation profiles between the two species (**Supplemental Table 5**). Alvarado et al. 2013 examined mouse PFC mRNA expression using RNAseq at 6-8 months post-SNI and identified 641 differentially expressed genes [22]. Our dataset was again enriched for genes identified by Alvarado et al. (hypergeometric test, $p = 8 \times 10^{-4}$), with 27 overlapping genes and 12 differentially methylated genes consistent with the predicted change in mRNA expression (**Supplemental Table 6**).

[**Figure 10: Identification and time course of differentially methylated CpGs associated with pain-related genes.** Displayed are CpG positions that were annotated to a pain-related gene identified by Ultsch, Kringel [271] or the Human Pain Genes Database (HPGD) [272]. **A)** For CpGs that were captured at all time points, pain-related genes show mostly single time point differential methylation. **B)** For CpG positions that were not captured at all time points, there is a trend towards single time point differential methylation. Values are displayed as differential methylation. ** = FDR adjusted p-value < 0.1. Grey = no data for that gene/time point*.]

The NMDA receptor subunit *Grin1* was identified in all three datasets, showing both consistent methylation across species and the predicted impact on mRNA expression. Gene regulatory gene *Eif3g*, and neurite outgrowth inhibitor *Rtn4* were among the genes consistent between M6 genes and Massart et al. Among the gene consistent between M6 and Alvarado et al. were the cell-cell junction desmosome gene *Dsg1c*, the actin regulatory gene *Cobl*, and the calcium/calmodulin dependent protein kinase *Camk1d*.

4. Discussion

This study evaluated DNA methylation as a mechanism for the long term embedding of injury-related pain in PFC and subsequent evolution of chronic pain. Previous studies have demonstrated DNA methylation responses to chronic pain in rodent PFC [22, 200], however a number of questions still remain. Are changes in DNA methylation a consequence of chronic pain or do changes precede its emergence? How rapidly do DNA methylation changes occur, and are they persistent throughout chronic pain's time course? Are these changes limited to pain genes, or do they affect entire domains and gene families? What can these changes tell us about how chronic pain develops and embeds itself? Finally, and most importantly, which of these processes should be targeted for intervention?

To answer these questions we tracked PFC DNA methylation profiles for one year post-SNI. We provide first evidence that the PFC methylome is reprogrammed immediately after injury at D1. These data, together with results showing rapid DNA methylation changes in dorsal horn and DRG after injury [236, 273], suggest DNA methylation changes precede the emergence of chronic pain. Second, we show SNI triggers a cascade of dynamic and evolving DNA methylation changes that continue up to one year post-injury, suggesting DNA methylation changes accompany the onset and establishment of chronic pain phenotypes. Third, we identified hundreds of genes and gene ontologies that experience differential methylation. While some may be relevant at only one time point, others are differentially methylated throughout the time course,

potentially serving as the genomic memory of the initial injury and necessary for chronic pain development.

4.1 CpG methylation dynamics

We first analyzed differential CpG methylation between Sham and SNI at each time point independently. At one day post-injury, we observed differential methylation of hundreds of specific CpG positions in the PFC. The D1 time point had the second largest proportion of differentially methylated CpGs identified and the largest average differential methylation, illustrating that the response of the PFC methylome to injury is rapid and substantial. Each time point evaluated had a large population of DM CpGs that displayed a substantial significant difference (FDR adjusted p-value < 1E-7) and large changes in differential methylation (> 40%), indicating strong methylation changes take place throughout the chronic pain time course.

The presence of both hyper-methylated and hypo-methylated CpG positions at each time point implies targeted regulation rather than genome-wide increases or decreases in methylation. There is also a slight trend towards overall promoter hyper-methylation, which may indicate a reduction in overall rates of transcription or a greater number of silenced genes. We previously observed that global DNA methylation decreases after SNI [22], however this difference can be explained by the non-specific demethylation of non-promoter regions in the genome.

4.2 Differentially methylated genes, pathways, and functions

We identified 1633 total unique genes that experience differential promoter methylation, of which 31 and 15 genes were members of the pain-related gene lists by Ultsch et al. or Human Pain Genes Database, respectively. Thus, chronic pain effects not just a few candidate genes but also functionally related groups of genes. Each time point had at least 300 differentially methylated genes identified, and over 150 enriched gene ontologies. At the early time points of D1 and W2, we observed a greater number of ontologies involved in the response to external stimuli, while at the later time points of M6 and 1Yr, inflammatory processes and T-cell adaptive immune responses are implicated. Interestingly, across all four time points numerous ontologies involved in actin dynamics or cytoskeletal regulation were identified. Actin reorganization has been previously identified as a key step in inflammation related persistent pain in glial cells in the spinal cord [274], and sensory neurons in the periphery [275]. The reorganization of nociceptive circuits and dendritic pruning in response to peripheral neuropathic pain is well established [100, 276, 277], and may be a form of maladaptive synaptic plasticity. The consistent differential methylation of actin and cytoskeleton related genes throughout the time course up to one year post-injury suggests an ongoing cortical plasticity and remodeling in response to peripheral injury, and that chronic pain induces progressively greater deviations from normal cortical functioning.

A number of our differentially methylated genes were consistent with results from previous studies. The NMDA receptor subunit *Grin1* was hypo-methylated in both mouse and rat PFC 6 and 9 months post-SNI respectively, with corresponding increases in Grin1

mRNA expression in mouse cortex during the same time frame [22, 200]. Other studies have demonstrated post-injury changes in PFC in NMDA receptor currents, and modulation of PFC NMDA activity can result in pain-attenuation [100, 278]. Hypo-methylation of Grin1 may drive pain-related neuroplasticity, and suggests that NMDA-dependent synaptic changes in chronic pain may be epigenetically-mediated. Other genes including *Camk1d, Kcnip2,* and *Cobl* were also consistent between differential methylation and mRNA expression. These converging lines of evidence across different studies highlight potentially pivotal pain-related genes.

4.3 Time point specific methylation patterns across the chronic pain time course

DM CpGs follow distinctive trajectories of differential methylation across the progression from acute to chronic pain. These differential methylation profiles are a time stamp for the contributions of each gene during chronic pain development and shed light on the post-injury response. Genes with DM CpGs that maintain a methylated state throughout the time course, such as *Wipf2, Rrp8, Xdh, or Sprr2d* may encode a persistent genomic memory of the initial injury, triggering and maintaining a chronic pain state.

It is important to also consider the time point specific differential methylation of genes. Nearly all identified pain-related genes were differentially methylated at a single time point, implying a time-dependent recruitment or dysregulation of normal functioning. *Grin1, Nrg1, Asic3, Gabrr1, Scn10a, Ramp1, Myd88, Trpv1, and Tnf* had differential methylation at only one observed time point. All have well documented impacts on pain

sensation across domains of ion channel activity and trafficking, inflammatory responses, and neurotransmitter regulation [279-293].

The time point specific gene differential methylation and ontology enrichment underscore the importance of understanding temporal dynamics and effects upon normal functioning during the transition to chronic pain. Here we describe the methylation response of the PFC across all phases of the pain phenotype. At one day post-injury, differential PFC methylation is likely driven by the acute abnormal sensory afferent signalling and systemic effects of peripheral inflammation. As pain becomes more chronic by two weeks post-injury, central mechanisms including central sensitization and neuroinflammation initiate changes in synaptic signalling and neuron-glia interactions in PFC. By six months and one year post-injury in late-stage chronic pain, dysregulation of descending inhibitory and facilitatory pain pathways, long-term neuroinflammation and neuroplasticity lead to characteristic depression, anxiety, cognitive impairment, and loss of PFC density.

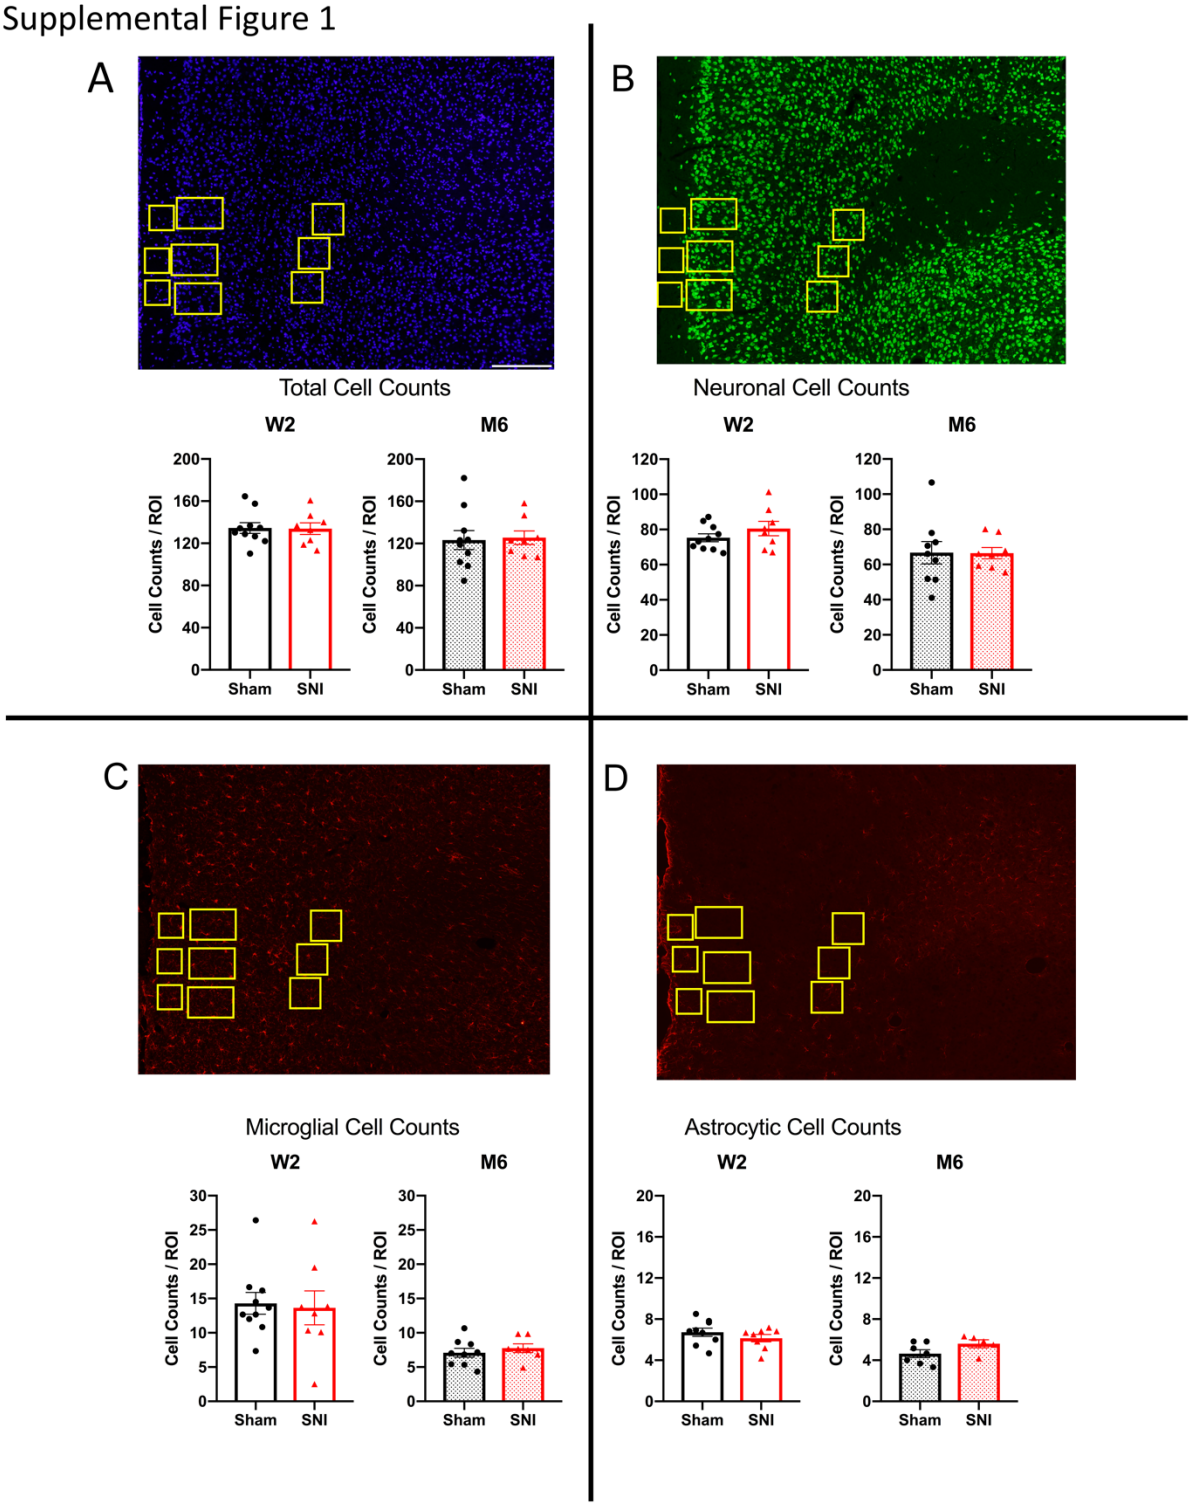
4.4 Limitations

First, only male mice were studied. Our results lack female methylation responses to chronic pain development, especially important given known sex differences in pain processing [294]. Second, our experiment focused on promoter region methylation, potentially missing DNA methylation regulation in non-promoter regions or by other processes. DNA methylation in the first intron of coding genes or gene body can affect gene expression [183, 295]. Moreover, DNA methylation does not have a linear

relationship to gene expression, with other regulatory processes such as RNA transcription or protein translation involved, thus requiring a future analysis of gene expression. Third, our tissue samples are derived from whole brain tissue homogenates, and therefore mixtures of different brain cell types, each with their own cell type specific profiles of DNA methylation. Thus, the differential methylation signal may be diluted by conflicting methylomic data. While the lack of significant changes in the proportions of neurons, astrocytes and microglia mitigates this limitation **(Figure 2),** changes in other non-neuronal cell types (e.g. oligodendrocytes, vascular cells) is not accounted for in the current study. Fourth, the alpha threshold was set at an FDR of 0.1 in this study. It is acknowledged that the selection of an FDR threshold of 0.1 carries a greater risk of type I error (false positive), it is preferable for the exploratory purposes of this study where type II error (false negative) is a greater concern. We recognize these limitations and present these results as a first step towards understanding the epigenetic reprogramming associated with the development and maintenance of chronic pain.

5. Conclusions

Our findings provide evidence for rapid epigenetic reprogramming in the PFC methylome in response to peripheral nerve injury. Thus, epigenetic reprogramming precedes rather than follows chronic pain, consistent with a causal role. Reprograming persists as pain becomes chronic, thereby suggesting an important role for DNA methylation in the initiation, progression and maintenance of chronic pain. While some changes in DNA methylation were persistent, dynamic reprogramming was also observed.



These patterns may reflect underlying differences between acute, sub-chronic and chronic pain, suggesting that therapeutic interventions may have efficacy dependent on pain duration. Pathway analysis revealed enrichment in genes related to stimulus response at early time points, immune function at later time points and actin and cytoskeletal regulation throughout the time course. These findings highlight the importance of understanding the time course of acute to chronic pain and suggesting broader pain interventions than single gene or protein targets are required.

Chapter 3: DNA Methylation Response to SAM Treatment of Chronic Pain

4.1. Preface

Chronic pain is associated with persistent changes in PFC structure and function. Previous work has demonstrated a clear association with DNA methylation in the PFC, the development and progression of chronic pain and the differential methylation of chronic pain-related functional domains. Interestingly, successful pain attenuation through therapeutic intervention reverses chronic pain associated losses in PFC grey matter in human patients. As a stable but malleable mechanism of gene regulation, DNA methylation is an excellent potential candidate mechanism to underlie this reversal in PFC. Indeed, research in addiction and stress have demonstrated that successful intervention will reverse DNA methylation changes associated with the disease. However, no study has determined gene specific changes in PFC DNA methylation in response to a successful pain attenuating intervention.

Previous work has demonstrated that chronic systemic administration of the methyl donor s-adenosylmethionine is capable of attenuating chronic peripheral neuropathic pain, and affecting global PFC DNA methylation levels. We hypothesized that chronic administration of s-adenosylmethionine would result in the counteraction or reversal of chronic pain related changes in PFC DNA methylation, and sought to determine affected functional domains.

4.2. Manuscript II:

Attenuation of neuropathic pain by s-adenosylmethionine is associated with genome-wide reversals of pathological changes in DNA methylation in mouse frontal cortex

Abstract:

Chronic pain is associated with persistent but reversible structural and functional changes in prefrontal cortex (PFC). This stable yet malleable plasticity implicates epigenetic mechanisms, including DNA methylation, as a potential mediator of chronic pain-induced changes. We have previously demonstrated that oral administration of the methyl donor s-adenosyl methionine (SAM) is capable of attenuating long-term peripheral neuropathic pain and affecting global PFC DNA methylation. However, little is known of the mechanisms underlying SAM-mediated pain attenuation. To elucidate these mechanisms, we performed epigenome-wide analysis of mouse PFC after 4 months of SAM treatment initiated 3 months following induction of peripheral nerve injury. Over 4000 differentially methylated genomic regions were detected in both Injury and SAM treatment conditions, and enriched gene ontologies included intracellular signaling, cell locomotion and migration, cytoskeletal structure, and cell adhesion. Following SAM treatment, 1415 differentially methylated regions, representing 1030 genes, showed a reversal of chronic pain-related differential methylation. Over 100 genes with known pain-related function were differentially methylated following nerve injury, with many also experiencing a reversal after SAM treatment. These results demonstrating the reversal of PFC DNA methylation concurrent with pain reduction underscore the potential of DNA methylation targeted therapies in treating chronic pain.

1. Introduction

The PFC is essential for executive function and synthesizing the diverse range of information the brain receives [296, 297], and is a crucial area for processing of nociceptive and aversive stimuli [298]. The PFC is part of a cortical and subcortical network that is activated by pain [14, 299] and may mediate its affective-motivational and cognitive components [300-302]. These higher-order aspects of pain can exacerbate an individual's perception of pain and contribute to pain-related comorbidities and reduced quality of life [37, 303-305]. As a result of chronic pain, the PFC undergoes structural and anatomical changes over time resulting in the loss of grey matter, reorganization of synaptic connections, and changes in gene expression [21-23, 100, 104].

Reduced PFC grey matter occurs in a number of different pain conditions in humans and animal models [15-20, 82]. Interestingly, treatments that attenuate pain are capable of reversing chronic pain-induced losses of cortical thickness or grey matter in the PFC [24-26, 86, 115]. PFC gene expression is also heavily modified in response to chronic pain with genome-wide changes in mRNA expression level detected in long-term neuropathic pain [22, 23]. The plasticity and possible reversibility of these changes is not only encouraging with regard to effectively treating chronic pain, but suggests the involvement of epigenetic mechanisms.

Epigenetic regulation of gene expression allows for malleable control over gene expression without modifying the underlying genetic sequence. DNA methylation is the covalent addition of methyl residues to cytosine nucleotides and when it occurs in the

promoter region of a gene, typically results in epigenetic repression of gene expression [243, 244]. DNA methylation is mediated by DNA methyltransferases (DNMT) and its methyl donating substrate, s-adenosylmethionine (SAM) [306, 307]. SAM is marketed as a nutritional supplement for a wide range of pain-related or comorbid conditions including depression, cognitive deficits, migraine, back pain and osteoarthritis [308-310].

A number of studies have demonstrated that chronic pain development is accompanied by changes in DNA methylation throughout pain transmission pathways including dorsal root ganglion [236, 311], spinal cord [312], and brain including PFC [22, 200, 234, 313]. Studies examining promoter region DNA methylation found gene-specific changes that correlated to mRNA transcript levels [200], and were dynamically regulated up to one year post-injury [313]. Moreover, successful attenuation of pain by environmental enrichment reduced global PFC DNA methylation levels in the PFC [22, 234]. However, no study has yet examined gene specific PFC DNA methylation after the effective treatment of pain.

We recently demonstrated that systemic chronic treatment with the methyl-donor SAM attenuated the sensory and cognitive impact of nerve injury in mice [234]. Here, we focused on understanding the impact of systemic SAM treatment at the molecular level via analysis of genome-wide PFC DNA methylation. We demonstrate that, consistent with previous findings, spared nerve injury (SNI) induces changes in DNA methylation. We further demonstrate that SAM treatment counteracts nerve injury-related changes in DNA methylation and we identify functional pathways affected by this reversal.

2. Materials and Methods

2.1 Animals

Male CD-1 mice (Charles River Laboratories, St-Constant, QC, Canada) were used in this study. Animals were received at 6-8 weeks of age and housed 3-4 per cage on a 12h light/dark cycle in a temperature controlled room in ventilated polycarbonate cages (Allentown, Allentown, NJ) with corncob bedding (7097, Teklad Corncob Bedding, Envigo, UK) and cotton nesting squares for enrichment. Mice were given access to food (2092X Global Soy Protein-Free Extruded Rodent Diet, Irradiated) and water *ad libitum*. Animals were habituated to the housing conditions for at least one week prior to any experimental interventions.

All experiments were approved by the Animal Care Committee at McGill University, and conformed to the ethical guidelines of the Canadian Council on Animal Care and the guidelines of the Committee for Research and Ethical Issues of the International Association for the Study of Pain [253].

2.2 Neuropathic pain model: Spared Nerve Injury

Animals were randomly assigned to receive either spared nerve injury (SNI) or sham surgery. Nerve injury was induced using the Spared Nerve Injury model of neuropathic pain, as adapted for mice [254, 255] at 10 to 12 weeks of age. Under deep isoflurane anesthesia, an incision was made on the medial surface of the thigh, exposing the three branches of the sciatic nerve. SNI surgery consisted of ligation and transection of the left tibial and common peroneal branches of the sciatic nerve, while sparing the

sural nerve. The tibial and common peroneal branches were tightly ligated with 4:0 silk (Ethicon) and sectioned distal to the ligation. Sham surgery consisted of exposing the nerve without damaging it.

2.3 Drug treatment: Chronic administration of s-adenosylmethionine

Three months after SNI or sham surgery, animals were randomly assigned to receive saline vehicle or SAM (kind gift of Life Science Labs Supplements, LLC, Lakewood, NJ) treatment for 4 months. A solution of SAM (20 mg/kg) was freshly prepared each treatment day in 0.9% NaCl, and each animal received an oral administration of 8 μL 3 times per week for 4 months. The chosen dose and the protocol used were influenced by previous studies [314-316].

2.4 Behavioural assessment of mechanical sensitivity

Baseline behavioral assessments were performed 3 months after SNI or sham surgery to confirm the development of neuropathic pain. Behavioural testing group sizes: Sham-Vehicle: n = 6, Sham-SAM: n = 6, SNI-Vehicle: n = 7, SNI-SAM: n = 8. Mechanical sensitivity was then reassessed every 2 weeks across the 4 months of treatment. After a 1 hour habituation period to the testing apparatus, von Frey filaments (Stoelting Co, Wood Dale, IL) were applied to the plantar surface of the hind paw until filaments were bent for either 3 seconds or hind paw withdrawal. Mechanical sensitivity was determined as the 50% withdrawal threshold using the up-down method [256]. The stimulus intensity ranged from 0.04 to 4.0 g, corresponding to filament numbers 2.44 to 4.56. The experimenter was blind to treatment group.

2.5 Isolation of prefrontal cortex, DNA capture, and bisulfite sequencing

Following completion of SAM treatment, mouse PFC was dissected following isoflurane anesthesia and decapitation. DNA methylation analysis group sizes: Sham-Vehicle: n = 3, Sham-SAM: n = 3, SNI-Vehicle: n = 4, SNI-SAM: n = 4. PFC was defined as a region with an anterior boundary of the frontal pole, approximately +3.00 Bregma, posterior boundary of approximately +1.00 Bregma, lateral boundaries of +1 mm from midline, and a ventral boundary wherein the olfactory bulb, caudate putamen, and areas below the rhinal fissure and lateral ventricles were all removed [257]. This defined area isolates the prelimbic, orbital, and infralimbic cortices corresponding to the mouse medial PFC. Once dissected, tissue was homogenized and genomic DNA was extracted using the Qiagen DNeasy Blood and Tissue kit and protocol.

Genome-wide methylation analysis was performed using the Roche SeqCap Epi Developer M Enrichment system on bisulfite-treated DNA (Roche Nimblegen; WI, USA), with custom designed primers targeting promoter and enhancer regions of the genome. Probe design was based on the mm9 reference genome and associated H3K4me1 and H3K4me3 binding (probe BED file available in **Supplemental Table 1**). Briefly, 1 μg of genomic DNA per sample was fragmented into 200bp lengths, and adapter and index sequences were ligated to each end of the fragment according to the KAPA Library Preparation Kit protocol. Sample DNA was then bisulfite converted following the EZ DNA Methylation-Lightning Kit (Zymo Research; CA, USA). Sample DNA was then PCR amplified, hybridized with custom capture probes, and PCR amplified again in accordance with Roche SeqCap Epi system protocols [259]. Sample captured bisulfite-converted

DNA sequencing was performed by Genome Quebec on the Illumina HiSeq 2500 following Illumina guidelines. Paired-end sequencing reads of 125bp in length were generated.

2.6 DNA methylation pre-processing

Capture sequencing data was pre-processed using the McGill University Genome Quebec Innovation Centre GenPipes Methyl-Seq Pipeline [260]. The pipeline proceeds through Trimmomatic, Bismark Align, Picard Deduplication, and Bismark Methylation Call [261, 262]. Baseline pipeline parameters were set as a minimum sequence quality of PHRED score > 30, alignment reference genome was mm10 (GRCm38), and minimum read coverage per base was set at 10 reads. A detailed outline of the Methyl-Seq pipeline steps and process can be found at https://bitbucket.org/mugqic/genpipes. Before analysis, collected sequence data was filtered to remove a blacklist of regions identified to have anomalous, unstructured, and high signal/read counts in next gen sequencing [263]. The blacklist used was specific for mm10 and the BED file can be found in **Supplemental Table 2.**

2.7 Differential methylation analysis

Differential methylation analysis was performed using R and the MethylKit package [317]. For a CpG site to pass through to analysis, it was required to be sequenced to a minimum depth of at least 10 reads in each sample. Coverage values between samples were normalized using a scaling factor derived from differences between the median of coverage distributions. Tiling windows were used to summarize methylation information over the genome. Tiles were set to be 250 base pairs (bp) in length and advance in 125

bp steps. Methylated and unmethylated cytosine counts within each tile are summed to provide an overall methylation proportion within the tile. Only CpGs that were annotated to a promoter region, defined as 2000 bp upstream or 200 bp downstream from the transcription start site, were selected for analysis. MethylKit uses logistic regression to model a log odds ratio based on methylation proportion within each tile. Calculated p-values are adjusted to q-values using the SLIM method [318].

Tiles were defined as being differentially methylated between groups if the adjusted p-value was less than < 0.1 and had a difference in methylation $> 5\%$. While the selection of an FDR threshold of 0.1 carries greater risk of type I error, false positive, than the more typical threshold of 0.05, it is preferable for the exploratory purposes of this study. Differentially methylated tiles can be further divided into hypermethylated or hypomethylated. In comparisons between groups, the control group acts as the reference point, i.e. Control: Sham-Vehicle, Experimental: SNI-Vehicle. Therefore, if the experimental group tile methylation is 5% or larger than the control, the tile is considered to be hypermethylated, and if the treatment tile methylation is reduced by -5% or more compared to control, the tile is considered to be hypomethylated.

Tiles were annotated to their associated genes and genomic regions using the annotatePeaks function of the ChIPseeker [265] R package, using a TxDb object created from the Gencode “mmusculus_gene_ensembl” Biomart database. Each tile position was annotated and tracked individually throughout the analysis. For homology conversion, gene symbols from non-mouse species were converted to known mouse homologs based

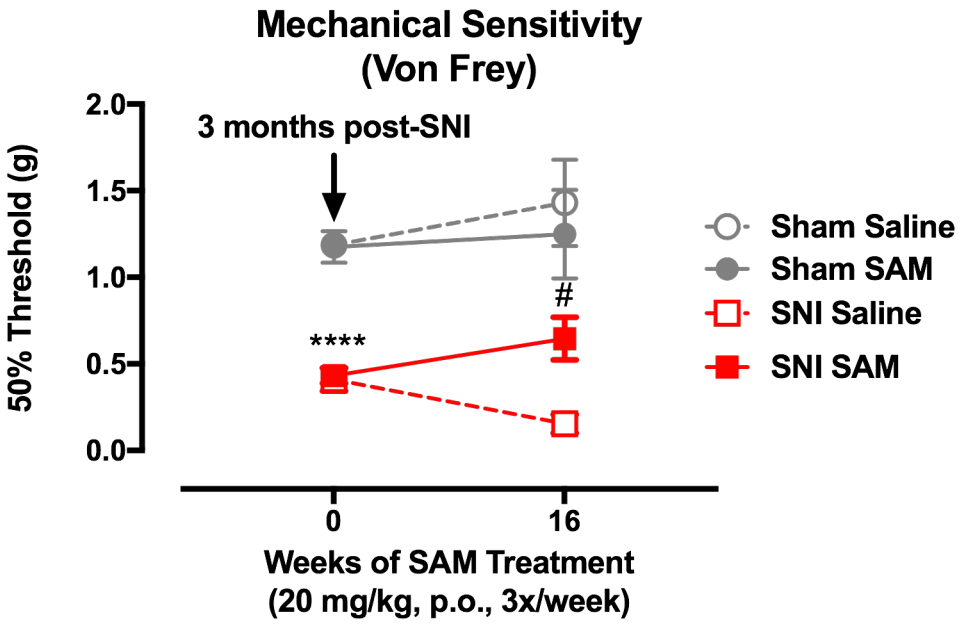
on the Mouse Genome Database (MGD) – Vertebrate Homology, Mouse Genome Informatics, The Jackson Laboratory, Bar Harbor, Maine [266].

To simplify the analysis of reversals in differential methylation, we filtered for genes that had uniform differential methylation, meaning all tiles annotated to the gene were all hypermethylated or all hypomethylated. Genes with variable differential methylation, where the gene simultaneously had some hypermethylated tiles and some hypomethylated tiles, were not examined in the reversal analysis.

2.8 Statistical analysis

Two-way repeated measures ANOVA with Bonferroni post-hoc test was used to detect group differences in the von Frey mechanical sensitivity behavioural assay. Pairwise comparisons of tiles between experimental groups utilized logistic regression to model the log-odds ratio of methylation proportion per tile. Analyses were corrected for multiple comparisons using the SLIM method [318]. The hypergeometric test was used to test for significant enrichment of pain-related genes.

2.9 Gene ontology analysis



Differentially methylated genes identified were submitted to gProfiler [319], a web-based gene ontology tool. The GO Biological Processes and Molecular Function databases were selected as ontology databases. Ontology p-values were adjusted using the g:SCS correction for multiple comparisons [320] and an ontology was considered enriched at an adjusted p-value < 0.05. To allow for a specific view of affected functions

and pathways, the displayed gene ontologies are limited to a maximum size of 2000 genes.

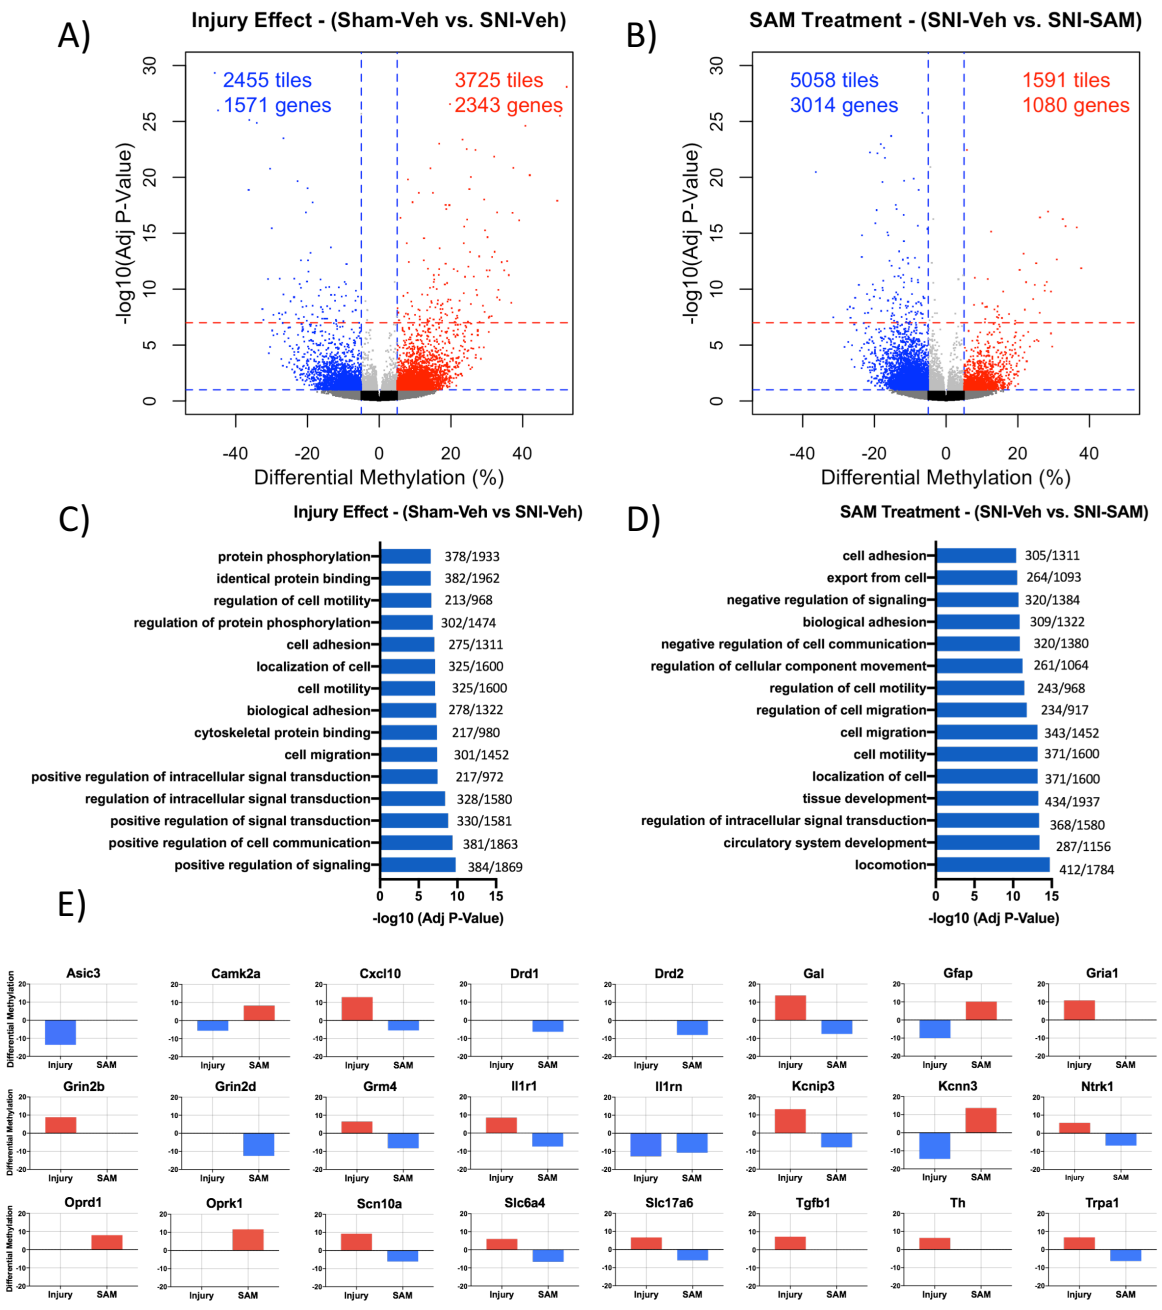
3. Results

3.1 Spared Nerve Injury results in mechanical hypersensitivity that is attenuated by chronic SAM treatment.

Pain hypersensitivity induced by SNI in mice occurs immediately and can persist for up to one year post-injury [313]. Chronic administration of methyl donor s-adenosylemethionine (SAM) 3 months post-SNI injury decreases mechanical hypersensitivity in the ipsilateral injured paw compared to saline vehicle treated animals (**Figure 1**).

[**Figure 1**: *Chronic systemic administration of s-adenosyl methionine attenuates peripheral neuropathic pain*. Repeated administration of SAM (20 mg/kg, oral gavage, 3 doses per week) over a 16 week period was initiated 3 months post- sham or SNI-surgery (Time 0). SNI-related mechanical hypersensitivity was attenuated compared to vehicle-treated animals. Sham-Vehicle: n = 6, Sham-SAM: n = 6, SNI-Vehicle: n = 7, SNI-SAM: n = 8. 2-way RM ANOVA with Bonferroni post-hoc test. ** : $p < 0.01$ sham-vehicle vs SNI-vehicle; # : $p < 0.05$ SNI-vehicle vs SNI-SAM. SNI: spared nerve injury; SAM: s-adenosylmethionine; p.o. : Per os (oral administration). Adapted from Gregoire et al. 2016 [234]]

3.2 Spared Nerve Injury and chronic SAM administration lead to widespread changes in DNA methylation in the prefrontal cortex



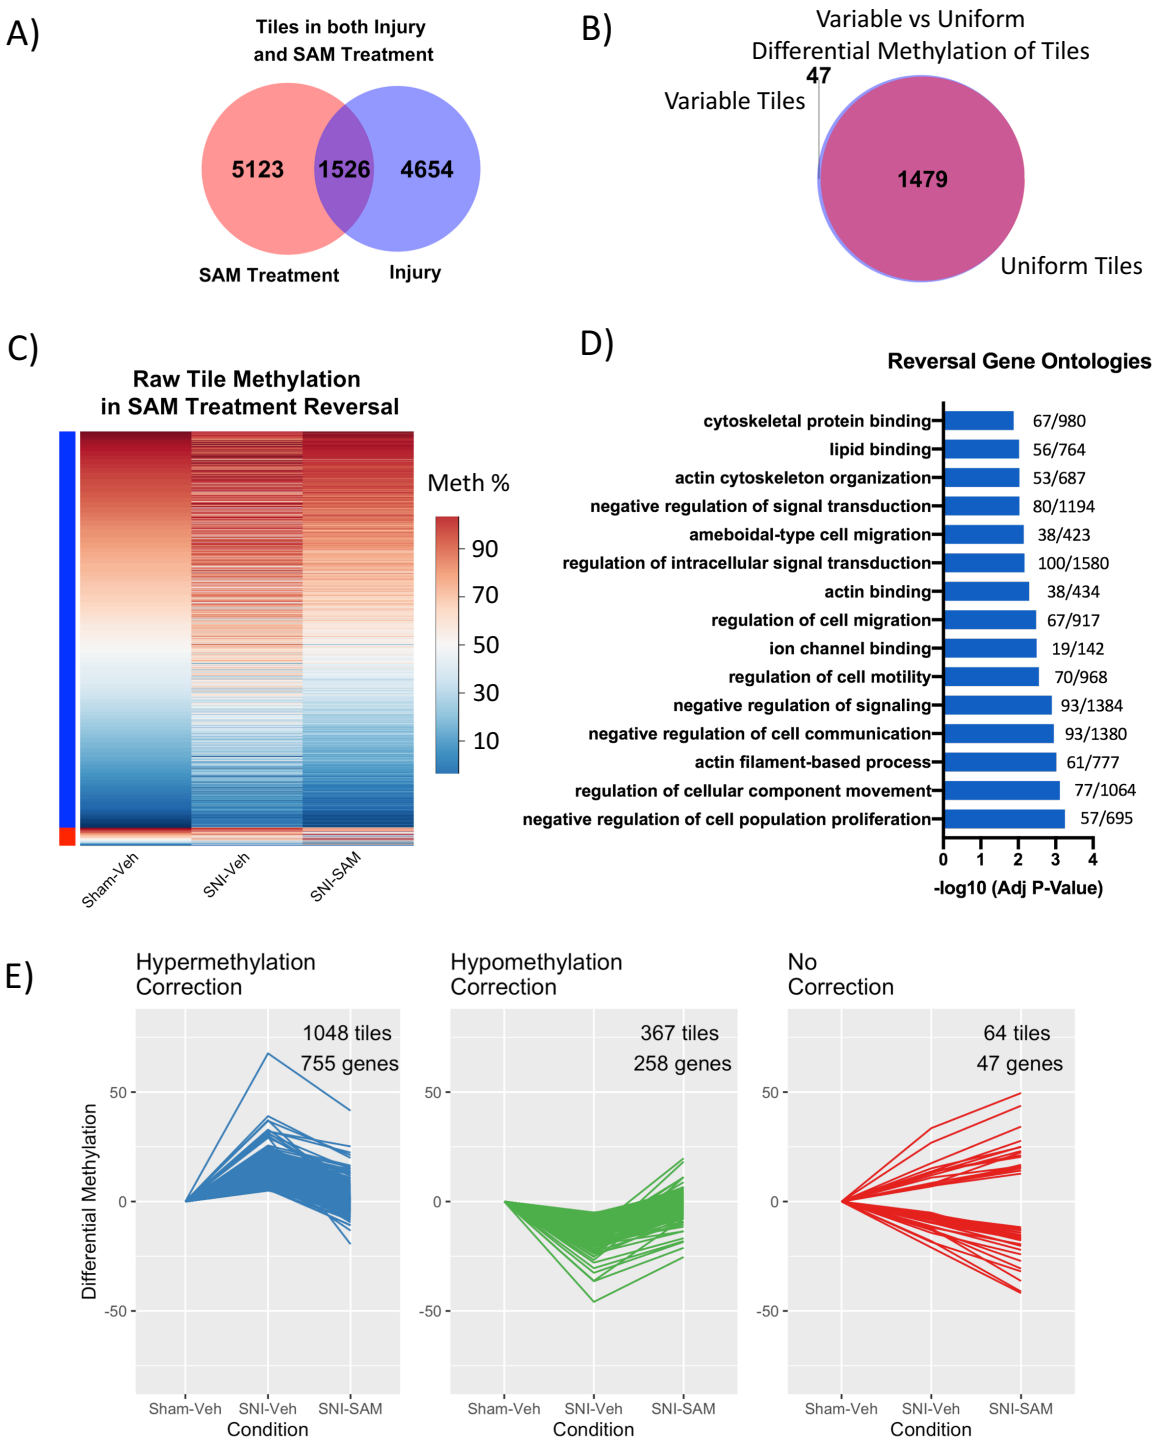
We have previously demonstrated changes in PFC promoter region methylation in response to SNI at multiple time points post-injury [313]. Here we examined global PFC promoter methylation post-injury and post-SAM administration to determine the effect of SAM on injury related changes in PFC promoter methylation.

To understand the effects of peripheral nerve injury, SNI-vehicle animals were compared against Sham-vehicle animals 7 months post-injury, with 191,013 tiling regions covering 22,683 unique gene promoters. We observed a trend towards promoter region hypermethylation with 3725 hypermethylated tiles and 2455 hypomethylated tiles, representing 2343 and 1571 unique genes, respectively (**Figure 2A**). 157 hypermethylated tiles and 95 hypomethylated tiles with robust differential methylation were detected (adjusted p-value < $1x10^{-7}$). These tiles represent 95 and 57 genes respectively and include PI3K gene *Pik3cd* (25.1% differentially methylated (DM)), toll-like receptor *Tlr6* (19.6% DM), and potassium ion channel subunit *Kcng2* (-29.9% DM). 213 ontologies were enriched for differentially methylated genes. The top 15 enriched ontologies are predominantly involved in signaling and intracellular signal transduction, cell migration, cytoskeletal protein binding, and biological adhesion (**Figure 2C**).

To explore the effect of SAM treatment in neuropathic pain, we compared SNI-SAM animals to SNI-vehicle animals, with 186,896 tiling regions evaluating 22,530 unique gene promoters. In contrast to sham vs. SNI, when SNI injured animals underwent chronic SAM administration, tiles in PFC promoter regions were predominantly

hypomethylated. 1591 hypermethylated tile regions and 5058 hypomethylated tile regions representing 1080 and 3014 unique genes were detected, respectively (**Figure 2B**). We detected 48 hypermethylated tiles and 142 hypomethylated tiles with robust differential methylation (adjusted p-value < $1x10^{-7}$). These tiles represent 33 and 78 genes respectively and include the TFIID subunit *Taf4b* (28.3% DM), interleukin 36β gene *Il1f8* (25.1% DM), and oxytocin receptor *Oxtn* (-9.6% DM). We identified 363 ontologies that were enriched in differentially methylated genes following SAM treatment. These ontologies are involved in locomotion and cell motility, circulatory system and tissue development, intracellular signal transduction, and cellular transport (**Figure 2D**).

To identify pain-related genes, differentially methylated genes were compared to curated lists of pain-related genes identified by Ultsch et al [271] or the Human Pain Genes Database (HGPD) [272]. Nerve injury resulted in differential methylation that was enriched for pain-related genes, with 110 differentially methylated pain-related genes identified by Ultsch and 59 differentially methylated pain genes identified by the HPGD (Ultsch: p = 0.0002; HPGD: p = 0.0103. Hypergeometric Test). In the SAM treatment effect, 112 DM pain genes were identified from the Ultsch list, and 62 from the HPGD list (Ultsch: p = 0.0012; HPGD: p = 0.0128. Hypergeometric Test). A number of pain related genes displayed reversals in differential methylation after SAM treatment, such as the CamKII subunit *Camk2a*, TrkA receptor *Ntrk1*, $Na_v1.8$ channel *Scn10a*, and serotonin transporter *Slc6a4* (**Figure 2E**).



[**Figure 2**: *Injury and SAM treatment induce strong changes in PFC DNA methylation across multiple functional pathways and pain-related genes*. The magnitude and statistical significance of promoter region tile differential methylation during A) Injury and B) SAM treatment of Injury. Tiles are displayed in terms of positive or negative methylation

difference with control as the reference point compared to experimental, against –log10(adjusted p-value). Blue horizontal dashed line indicates an adjusted p-value threshold of 0.1, red horizontal dashed line indicates an adjusted p-value threshold of $1x10^{-7}$. The blue vertical dashed line indicates methylation difference thresholds of 5% and -5%. Red: hypermethylated; blue: hypomethylated; dark grey: non-significant but with methylation differences of > 5%; light grey: significant but with methylation differences of < 5%, black = not different. The top 15 enriched gene ontologies for differentially methylated genes in C) Injury and D) SAM treatment. Displayed ontologies are filtered for a maximum size of 2000 genes and are from Biological Processes or Molecular Function domains. Listed are the number of differentially methylated genes / total number of genes in each ontology E) Differential methylation of 24 pain genes of interest where displayed differential methylation is the average of all identified tiles per gene. Hypermethylated pain genes are displayed in red, hypomethylated genes are displayed in blue. Pain genes have been previously identified by either Ultsch et al. 2013 [271] or the Human Pain Genes Database [272]. Sham-Vehicle: n = 3, SNI-Vehicle: n = 4, SNI-SAM: n = 4.]

3.2 SAM treatment is associated with a reversal of SNI-induced differential methylation

To further understand the effect of SAM on injury-driven changes in DNA methylation, we identified 1526 tile regions that experience differential methylation in both injury effect and SAM treatment comparisons (**Figure 3A**). Of these 1526 tiles, 1479 tiles (representing 1030 genes) had uniform differential methylation when annotated to their gene, while 47 tiles (15 genes) had variable differential methylation (**Figure 3B**). After

isolating tiles that were uniformly differentially methylated, we found 1415 tiles (1030 genes) where injury-induced changes in DNA methylation were reversed by SAM treatment, while 64 tiles (47 genes) experiencing no reversal post SAM-treatment (**Figure 3C**). Of the 1451 reversing tiles, 1048 tiles (755 genes) are initially hypermethylated during the injury, and experience hypomethylation during SAM treatment, while 367 tiles (258 genes) are hypomethylated during injury and hypermethylated during SAM treatment (**Figure 3E**). Gene ontology analysis revealed that promoter regions that undergo a reversal after SAM treatment are enriched in domains of cell migration, cell signalling and communication, and actin cytoskeleton structure (**Figure 3D**). Promoter regions that did not reverse after SAM treatment did not associate with any gene ontology.

[**Figure 3:** *SAM Treatment is associated with the reversal of chronic pain induced DNA methylation*. A) 1526 tiles are differentially methylated in both Injury and SAM Treatment. B) Of those 1526 tiles, 1479 are uniformly differentially methylated where all tiles

associated to a single gene are all hypermethylated or hypomethylated. 47 tiles show variable differential methylation. C) 1415 tiles show a reversal in differential methylation from Injury (Sham-Veh vs SNI-Veh) to SAM Treatment (SNI-Veh to SNI-SAM), and 64 tiles experiencing no reversal. Side Column: Blue = reversal, red = no reversal. D) Top 15 gene ontologies associated with reversing genes. Displayed ontologies are filtered for a maximum size of 2000 genes and are from Biological Processes or Molecular Function domains. Listed are the number of differentially methylated genes / total number of genes in each ontology. E) Reversing tiles are predominantly hypermethylated by injury and then hypomethylated by SAM. Sham-Vehicle: n = 3, SNI-Vehicle: n = 4, SNI-SAM: n = 4. SAM: s-adenosyl methionine; DM: Differential methylation.]

3.3 SAM Treatment corrects SNI-induced differential methylation at key junctures in the Ras signalling pathway

The enriched gene ontologies that were influenced by nerve injury and reversed by SAM were predominantly in domains of cellular signal transduction, cell motility and locomotion, cytoskeletal and actin organization, and tissue development. The Ras signalling pathway (KEGG 04014) is involved in many of these domains, and key hubs were reversed of differential methylation after SAM treatment (**Figure 4A**). We detected 77 genes in the Ras signalling pathway that were differentially methylated in either Injury or the SAM treatment, which act on 39 different nodes in the Ras signalling pathway (**Figure 4B**). 12 nodes in the pathway display a reversal of differential methylation as a result of SAM treatment, including the key hub node of Ras and transduction nodes RhoA,

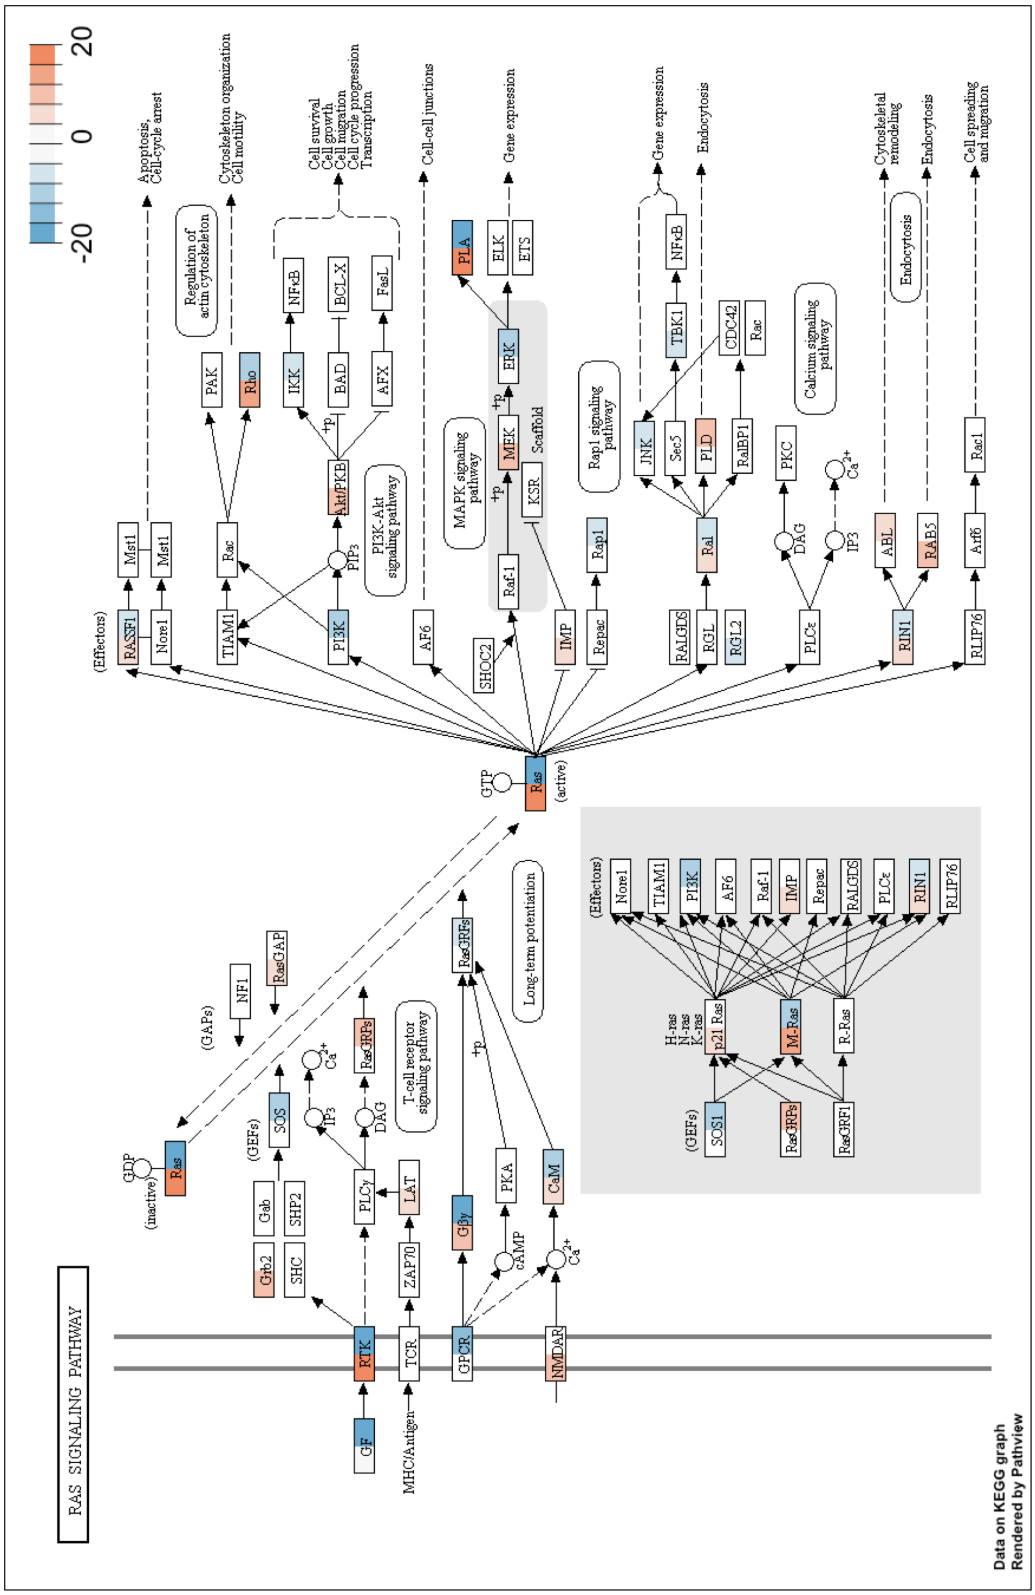
RIN1, and Ral. A single node can represent a number of genes which have the same or similar function within the pathway.

The classical transduction pathway for Ras signalling is for extracellular ligands such as growth factors (GF) to activate receptor linked tyrosine kinases (RTK). Activation of RTKs lead to binding of docking proteins such as Grb2 and SOS, and subsequent downstream activation of Ras proteins through GTP exchange. Ras proteins function as molecular switches for numerous downstream processes such as cell proliferation, differentiation, adhesion and migration, as well as regulating actin cytoskeletal structure. Our data shows differential methylation across the three major aspects of this pathway: extracellular signal transduction, Ras and Ras-related guanine exchange factors (GEF) and GTPase activating proteins (GAP), and downstream effectors.

At the level of extracellular transduction, we identified 18 different GFs and 12 different RTKs that undergo differential methylation either after injury or SAM treatment, with 5 GFs and 5 RTKs experiencing a SAM associated correction of injury differential methylation. GFs and RTKs were predominantly hypermethylated in injury and hypomethylated in SAM treatment, with a few exceptions (*Fgf15, Fgf2, Fgf22, Igf2, Fgfr4, Pdgfrb*) (**Figure 4C**). The downstream effectors of RTKs, *Grb2* and *SOS1*, were hypermethylated in injury and hypomethylated in SAM treatment respectively.

We identified three separate Ras genes which undergo differential methylation, *MRas, HRas*, and *RRas2*. *MRas* is hypermethylated in injury, and hypomethylated in SAM treatment (**Figure 4C**), while *HRas* and *RRas2* are only hypermethylated in injury or hypomethylated in SAM treatment respectively. Ras proteins are activated by GEFs,

which replace Ras-bound GDP with GTP, and inactivated by GAPs, which activates Ras GTPase activity and returns Ras to an inactive Ras-GDP state. We identified 2 differentially methylated RasGEFs, *Rasgrf1* and *Rasgrp2*, which are hypomethylated and hypermethylated respectively, both in the SAM treatment condition. We also identified a differentially methylated RasGAP, *Rasa1*, which is hypermethylated after injury.



Ras proteins activate numerous effectors such as TIAM1, Rin1, Rgl, PI3K, Repac, and Raf-1 which in turn regulate downstream processes or cellular functions. A number of these effectors or their downstream targets were differentially methylated after injury or SAM treatment. Ras affects the MAPK/ERK signalling pathway, a major regulator of gene expression, through Raf-1 activity and both MEK gene *Map2k1* and ERK gene *Mapk3*, are hypermethylated after injury and hypomethylated after SAM treatment respectively. Other differentially methylated effectors or downstream targets involved in gene expression regulation include Ral gene *Ralb*, JNK gene *Mapk9,* and *Tbk1*.

Processes of cytoskeleton remodeling and cell motility are mediated through *Rin1* and TIAM1 / Rac in the Ras signalling pathway, with differential methylation of *Rin1,* and downstream Rho-related gene *4930544G11Rik* detected (**Figure 4C**). Other differentially methylated cytoskeletal structure or cell motility genes not shown include mDia gene *Diaph1,* myosin light chain genes *Myl2, Myl9, Myl10,* gelsolin genes *Gsn* and *Scin,* and ERM genes *Ezr* and *Rdx*.

Finally, Ras can affect the PI3K-AKT-mTOR signaling pathway, responsible for cell cycle regulation and proliferation. The PI3K gene *Pik3r2* and AKT gene *Akt1* are both

differentially methylated in the Ras signalling pathway, as well as non-Ras pathway PI3K genes *Pik3cg* and *Pik3r5*. Downstream of AKT, CREB genes *Atf6b, Creb1,* and *Creb5* are all hypomethylated after SAM treatment, while CREB gene *Creb3l4* is hypermethylated after injury. The mTOR signalling pathway is also affected, with Raptor gene *Rptor,* and Raptor stabilizing complex genes *Tel2* and *Tti1* showing injury related hypermethylation and SAM treatment related hypomethylation. Interestingly, Deptor gene *Deptor* is hypomethylated in both conditions. Downstream of mTOR activity, protein synthesis related genes *Eif4ebp1*, *Eif4e*, *Rps6kb2,* and *Eif4b* are all hypomethylated after SAM treatment, with only *Eif4b* showing injury related hypermethylation.

4. Discussion

We have previously demonstrated that SAM chronic treatment attenuates nerve injury-related mechanical sensitivity as well as injury-related cognitive deficit [234]. Given the difficulty of developing novel therapies against chronic pain, we explored the mechanisms underlying SAM-related attenuation to identify potential avenues of treatment. Our current study supports SAM's ability to reverse chronic pain-induced changes in PFC DNA methylation and examines those effects at the level of individual genes and gene pathways.

First, we confirmed previous findings of differential PFC methylation many months following nerve injury [22, 200, 313] and differential methylation in response to chronic systemic SAM administration [234]. We identified over 3500 differentially methylated genes after either injury or SAM treatment, indicating that both states are capable of inducing widespread PFC methylation changes. Second, we showed the reversal of injury-related differential methylation after SAM treatment concurrent with pain

attenuation. This is consistent with work from other domains where reduction of a disease state with treatment is capable of reversing methylation patterns [322, 323]. Finally, we found that these reversals occurred at a number of key junctures in the Ras signalling pathway. These reversals reflect a substantial reorganization of cellular functioning during injury and SAM treatment, and potentially influencing LTP and other pain-related functions. These changes and subsequent reversals of DNA methylation in pain relevant domains support the potential of targeting of epigenetic mechanisms to treat and alleviate chronic pain.

4.1 PFC Methylation Response to Injury and SAM

Both neuropathic pain and SAM treatment are capable of inducing widespread and highly significant changes in PFC methylation, with each condition inducing differential methylation in nearly 17% of the ~22,500 genes examined. We observed regions with differential methylation of up to 40% and an adjusted p-value of less than $1x10^{-7}$. In comparison, human fetal brain methylation during development changes by up to 80% per year while methylation change as a result of aging changes by 1% per year as a child or 0.01% as an adult [324]. These widespread changes demonstrate not only the global impact of chronic pain but also the responsivity of the PFC methylome to environmental states.

At 7 months post-injury, we observed a slight trend towards hypermethylation when comparing between Sham-Vehicle and SNI-Vehicle groups. This is consistent with previous observations of PFC hypermethylation during chronic pain at multiple time points

after SNI [313], or 3 weeks after spinal nerve ligation [236]. Injury induced hypermethylation would imply increased gene repression in response to injury. Indeed, in studies of PFC mRNA expression after injury, Alvarado et al. 2013 found decreases in mRNA expression in mouse PFC six months after SNI (278 upregulated genes to 367 downregulated genes)[22], and Descalzi et al. 2017 found similar results 2.5 months after SNI in mouse medial PFC (179 upregulated to 204 downregulated genes). This consistent trend across studies may indicate the promotion of hypermethylation in chronic pain, potential mechanisms include an increase of aging related methylation [325, 326]. While a hypermethylation trend may reveal how DNA methylation responds during chronic pain, both hypermethylated and hypomethylated genes must be considered when identifying disrupted functions.

We observed a trend towards hypomethylation following SAM treatment of SNI animals. This result is surprising, as SAM is the primary methyl donating substrate for DNA methyltransferases (DNMTs) and would therefore be expected to increase methylation. Indeed, we previously established that chronic administration of SAM significantly increases global methylation in PFC post-injury [234]. There are a number of explanations why systemic SAM treatment would decrease methylation in promoters while increasing global methylation. SAM is not only a methyl donor to DNMTs but is the primary methyl donor to most methyltransferase enzymes such as histone methyltransferases or catechol-O-methyltransferase [327-330]. Histone methylation at different histone tail positions can recruit chromatin modifying complexes and result in either open or closed chromatin conformation and corresponding changes in DNA

methylation [215]. Therefore increases in SAM availability could lead to altered histone methylation patterns with increased H3K4 or H3K36 methylation associated with open chromatin and hypomethylation and increased H3K9 or H3K27 methylation leading to closed chromatin and hypermethylation [215, 331]. Moreover, the SAM metabolite s-adenosylhomocysteine (SAH) is an inhibitor of most methyltransferases [332, 333], therefore increased administration of SAM may lead to an accumulation of SAH.

4.2 Differentially Methylated Functional Domains in Injury and SAM

Following nerve injury, differentially methylated genes are enriched for domains of intracellular signalling, cell motility and locomotion, cellular adhesion, and cytoskeletal formation. These domains confirm previous observations of differentially methylated functions in PFC after neuropathic injury [200, 313]. Following SAM treatment, differentially methylated genes are enriched in similar functional domains observed in injury, primarily those related to locomotion and cell motility, intracellular signalling and signal transduction, and cell adhesion. SAM treatment was also enriched for differentially methylated genes involved in tissue development, and cellular export. These enriched domains indicate different potential mechanisms involved in late-stage chronic pain and SAM treatment reversal.

The presence of similar differentially methylated functional domains following both injury and SAM treatment imply that similar mechanisms are involved in late stage chronic pain maintenance and recovery. In injury, 60-65% of differentially methylated genes within each ontology are hypermethylated, whereas in SAM treatment, 75-80% of differentially

methylated genes are hypomethylated. Thus functional pathways in injury may be slightly repressed overall. However it is important to consider what stage of a functional pathway is differentially methylated. For example, if the hypermethylated genes are concentrated in branches of the pathway that are largely inhibitory, then overall pathway activity would be potentiated. Similarly, while functional pathways are more disposed towards hypomethylation following SAM treatment, we cannot conclude the impact on overall activity of a pathway without considering the function of the individual genes.

4.3 Differential Methylation of the Ras Signalling Pathway

Intracellular signalling pathways are involved in a multitude of functions in chronic pain, however we examined the Ras signalling pathway in detail. The Ras-MAP kinase (MAPK) signalling pathway undergoes significant differential methylation following both injury and SAM treatment. Differential methylation of the Ras-signalling protein MRas, and MAP kinases MEK and ERK could potentially affect protein translation regulation [334]. Differential methylation of Rin1 and Rho family member 4930544G11Rik could affect actin cytoskeletal organization, cell migration, and synaptic plasticity [335-337]. Neuronal MAPK activity via the ERK1/2 branch in primary nociceptive afferents and spinal dorsal horn is required for the induction and maintenance of both peripheral and central sensitization [338, 339]. Astrocyte and microglial MAPK activity in the ERK1/2, p38, and JNK branches have also been observed in spinal cord after the onset of chronic pain [340-343]. In neurons, MAPK activity via Ras-ERK1/2 is necessary for the insertion of AMPA-R subunits during long term potentiation (LTP) [344]. Supraspinal MAPK pathway activation is also noted in amygdala, anterior cingulate cortex, and PFC after peripheral

injury [345-347], with neuronal phospho-ERK1/2 upregulation specifically noted in medial PFC [348].

4.4 PFC Methylation Reversal after SAM Treatment

Changes in DNA methylation in response to external stimuli are well established, and a number of studies have previously reported reversals in disease or condition related DNA methylation after successful treatment [322, 323, 349]. We are the first study to investigate epigenome-wide reversals in chronic pain DNA methylation after effective attenuation of pain. We demonstrate that an intervention which attenuates mechanical hypersensitivity after onset of neuropathic pain also induces the reversal of injury-driven changes in DNA methylation at hundreds of gene promoters. After identifying differentially methylated tiles that were present in both Injury and SAM treatment analyses, nearly all (1415/1479) tiles displayed a reversal in differential methylation. This is an incredible finding as it represents over 1000 genes changing towards an uninjured methylation status after a successful intervention. Proportionally, it represents ~5% of the mouse genome or ~25% of genes that were differentially methylated post-injury. These may be a critical subset of genes responsible for mediating chronic pain's impact upon the brain. Indeed, these genes are enriched in domains of intracellular signalling, actin and cytoskeletal structure, cell migration, and ion channel binding, which have been proposed to underlie chronic pain related decreases in grey matter and subsequent recovery after treatment in humans [118, 298, 350].

In this study, promoter methylation was typically increased by injury and decreased after treatment. However, SAM treatment in SNI animals typically did not fully reverse DNA methylation to levels matching those observed in control uninjured, vehicle-treated mice. Thus, while SAM treatment is capable of attenuating pain-related differential methylation, it was generally not sufficient to return the animals to the equivalent of a non-chronic pain state.

4.5 Limitations

When considering this study, a number of limitations must be considered. First, our results are exploratory. As a result, the group size of 3-4 animals is low and we selected a permissive adjusted p-value of 0.1 in order to reduce the likelihood of false negatives. Second, our study focused on promoter region methylation; methylation at distal enhancers and within the gene body is also known to play a role in regulating gene transcription [183, 295, 351]. While promoter region methylation is a dominant mechanism of DNA methylation regulation, there are a number of other mechanisms that influence gene transcription, translation, and ultimately expression. Third, the chronic systemic administration of SAM may affect the sensation of chronic pain via mechanisms unrelated to DNA methylation. As stated above, SAM also is a methyl donor for histone methyltransferases and COMT, which both have well-established impacts upon pain sensation. Fourth, our study contained males only therefore our conclusions do not account for sex differences in response to chronic pain. However, we recognize these limitations and believe our results provide an important first look into the plasticity of PFC DNA methylation after successful treatment for chronic pain.

5. Conclusions

Our findings provide first evidence for epigenome-wide reversal of pain-induced differential DNA methylation after treatment in an animal model of chronic pain. These changes primarily occurred in domains of intracellular signaling, cell motility and locomotion, and cytoskeletal structure, reflecting potential changes in translational control, astrocyte and microglial activity, and synaptic pruning and formation. DNA methylation has a clear relationship with chronic pain and may contribute to the cortical recovery observed after therapeutic interventions. These findings provide a crucial insight to the effect of chronic pain on the prefrontal cortex, and potentially reveals mechanisms of how the brain is able to recover.

Chapter 4: DNA Methylation Response to Exercise Treatment of Chronic Pain

5.1. Preface

Exercise is a frequently recommended prescription for the relief of chronic pain, and in recent years non-pharmacological interventions have become increasingly recommended in lieu of pharmacological treatments when addressing chronic pain. Exercise effectively reduces pain sensitivity and improves cognitive functioning and PFC health. In particular, exercise can induce increases in brain volume in both healthy individuals and those suffering from chronic illnesses. Moreover, exercise also impacts DNA methylation in the brain. The previous manuscripts and other research has established the correlation between the development and treatment of chronic pain and altered PFC DNA methylation. However, it is unknown what effect treating chronic pain with a non-pharmacological exercise intervention will have upon PFC DNA methylation. Examining PFC DNA methylation in response to a non-pharmacological exercise intervention will broaden our understanding of the relationship between PFC DNA methylation and chronic pain, and clarify the potential of DNA methylation as a therapeutic target.

In this study, we hypothesized that access to voluntary running exercise would attenuate neuropathic pain in a mouse model, and counteract or reverse chronic pain associated changes in PFC DNA methylation.

5.2. Manuscript III:

Voluntary exercise attenuates chronic neuropathic pain and reverses nerve injury-induced modifications in DNA methylation in mouse frontal cortex.

Abstract:

Exercise is a commonly prescribed non-pharmacological intervention for chronic pain with demonstrated benefits in reducing pain and improving quality of life. Chronic pain is associated with reversible changes in cortical thickness and altered epigenetic regulation; exercise has been shown to impact both of these phenomena. We hypothesized that therapeutic exercise attenuates pain-related epigenetic modifications in the brain. To explore the epigenetic response to exercise in chronic pain, we provided voluntary access to home cage running wheels for 4 months, eight months after induction of neuropathic pain via Spared Nerve Injury (SNI) in male mice. Home cage running wheel exposure attenuated SNI-induced mechanical sensitivity. Epigenome-wide analysis of DNA methylation in prefrontal cortex (PFC) was employed to identify PFC epigenetic response and underlying mechanisms. Over 5000 differentially methylated regions were detected following both SNI and exercise intervention, representing nearly 4000 unique genes in each. Differentially methylated genes following both SNI and exercise intervention were significantly enriched in gene ontologies for ion transport and homeostasis, cell adhesion, and locomotion. SNI also resulted in enrichment for domains in cell death and actin cytoskeleton, while exercise also resulted in enrichment for domains in immune function and morphogenesis. 1199 differentially methylated regions, representing 856 genes, reversed their chronic pain-induced differential methylation as a result of voluntary running. These reversing genes were enriched in domains of vascular endothelial growth factor signalling, biological adhesion, and tissue development. We also found over 150 differentially methylated genes in SNI mice with known pain-related

functions, many of which were reversed by exercise. We demonstrate the effectiveness of a non-pharmacological intervention against chronic pain that reduced mechanical hypersensitivity and reversed many pain-driven changes in DNA methylation. These results underscore the role of DNA methylation in maintaining chronic pain and highlight underlying mechanisms and potential novel therapies to successful pain treatment.

1. Introduction

Exercise is a central component of many treatment plans for chronic pain, and is frequently recommended in advance of pharmacological interventions [137, 352]. Exercise can be effective against a number of chronic pain conditions, yielding effective reductions in pain sensitivity [136, 353-355]. Exercise also improves a number of chronic pain comorbidities such as physical functioning and conditioning [356-358], sleep and fatigue [359, 360], and mood disorders [361-363]. Importantly these benefits persist long after exercise has been stopped, providing long-term relief of symptoms, positive reinforcement to improve compliance, and a continuing method for individuals to manage their symptoms outside of clinical care [141, 364, 365].

Given the benefits, understanding the mechanisms of exercise-based treatments on chronic pain is crucial. In healthy individuals, exercise improves cognitive functioning and prefrontal cortex (PFC) health [366-369], two areas that are adversely affected by chronic pain. During chronic pain, the PFC undergoes a number of structural and anatomical changes that result in the loss of grey matter and cortical thickness, reorganization of synaptic connections, and changes in gene expression [21-23, 100, 104]. A number of human and animal studies have demonstrated the loss of PFC grey matter across different pain models and conditions [15-20, 82]. Interestingly, treatments that attenuate pain are capable of reversing this loss [24-26, 86, 115]. Chronic pain also affects PFC gene expression with transcriptome-wide changes in mRNA expression level detected in long-term neuropathic pain [22, 23]. The plasticity and reversibility of these

changes is not only encouraging with regard to effectively treating chronic pain, but suggests the involvement of epigenetic mechanisms.

Epigenetic regulation is a mechanism by which gene expression can be stably but flexibly controlled without modifying the underlying genetic sequence. The process of DNA methylation involves the covalent addition of a methyl residue to cytosine nucleotides. When it occurs in the promoter region of a gene, it commonly results in repression of gene expression via interference with general and specific transcription factors [243, 244]. Chronic pain development is associated with PFC DNA methylation changes in animal models of chronic pain [22, 200, 234, 313]. Studies examining promoter region DNA methylation found gene-specific changes in DNA methylation, which correlated to mRNA transcript levels [200], and that these changes showed dynamic patterns of regulation up to one year post-injury [313]. Moreover, successful attenuation of pain was found to reduce global PFC DNA methylation levels in the PFC [22, 234].

Given this profile of structural and functional changes, loss of PFC grey matter, and changes in gene expression and epigenetic regulatory pathways, aerobic exercise is particularly interesting as it impacts these mechanisms. Aerobic exercise induces increases in brain volume correlated to the level of physical fitness in both healthy individuals and patients suffering from chronic illnesses [370-373]. Aerobic exercise also impacts epigenetic regulation of the brain, causing differential DNA methylation and histone modification [374-377]. However, there has yet to be research on the response

of PFC DNA methylation to an aerobic exercise therapy provided in treatment of a long-term chronic pain.

To explore the impact of exercise upon long-term chronic pain, we provided aerobic intervention eight months after neuropathic injury and collected genome-wide PFC DNA methylation after four months. First, exercise intervention significantly reduced mechanical hypersensitivity when provided 8 months post-injury. Second, our results demonstrate corresponding strong and robust changes in PFC DNA methylation with 5251 differentially methylated regions in SNI and 6247 differentially methylated regions after exercise intervention. Differentially methylated genes in SNI mice were enriched in domains of Ion transport and homeostasis, cell adhesion, and locomotion and motility, while differentially methylated genes after Exercise Intervention were enriched in domains of ion transport and homeostasis, locomotion and motility, immune response, and morphogenesis. Finally, the exercise intervention induced the reversal of chronic pain related differential methylation of 1241 regions.

2. Materials and Methods

2.1 Animals

Male CD-1 mice (Charles River Laboratories, St-Constant, QC, Canada) were used in this study. Animals were received at 6-8 weeks of age and housed 3-4 per cage on a 12h light/dark cycle in a temperature controlled room in ventilated polycarbonate cages (Allentown, Allentown, NJ) with corncob bedding (7097, Teklad Corncob Bedding,

Envigo, UK) and cotton nesting squares for enrichment. Mice were given access to food (2092X Global Soy Protein-Free Extruded Rodent Diet, Irradiated) and water *ad libitum*. Animals were habituated to the housing conditions for at least one week prior to any experimental interventions.

All experiments were approved by the Animal Care Committee at McGill University, and conformed to the ethical guidelines of the Canadian Council on Animal Care and the guidelines of the Committee for Research and Ethical Issues of the International Association for the Study of Pain [253].

2.2 Neuropathic pain model: Spared Nerve Injury

Animals were randomly assigned to receive either spared nerve injury (SNI) or sham surgery. Nerve injury was induced using the Spared Nerve Injury model of neuropathic pain, as adapted for mice [254, 255] at 6 to 8 weeks of age. Under deep isoflurane anesthesia, an incision was made on the medial surface of the thigh, exposing the three branches of the sciatic nerve. SNI surgery consisted of ligation and transection of the left tibial and common peroneal branches of the sciatic nerve, while sparing the sural nerve. The tibial and common peroneal branches were tightly ligated with 4:0 silk (Ethicon) and sectioned distal to the ligation. Sham surgery consisted of exposing the nerve without damaging it.

2.3 Exercise Intervention: Running Wheels

Eight months after SNI or sham surgery, animals were randomly assigned to receive exercise intervention or control. Exercise intervention was provided for 4 months.

Exercise intervention consisted of a running wheel placed in the home cage which could be accessed *ad libitum*. The wheels consisted of a spinning saucer-like wheel mounted on a dome shaped hut for nesting (InnoDome™ and InnoWheel™, Bio-Serv, Flemington, NJ). Control animals received the same running wheel and hut but with a screw placed to prevent the wheel from spinning. Group sizes: Sham-Sedentary: n = 8, Sham-Running: n =17, SNI-Sedentary: n = 9, SNI-Sedentary: n = 9.

2.4 Behavioural assessment of mechanical sensitivity

Behavioral assessments were performed 8 months after SNI or sham surgery to acquire a baseline of neuropathic pain, and then animals were reassessed every month for the 4 months of intervention. After a 1 hour habituation period to the testing apparatus, von Frey filaments (Stoelting Co, Wood Dale, IL) were applied to the plantar surface of the hind paw until filaments were bent for either 3 seconds or hind paw withdrawal. Mechanical sensitivity was determined as the 50% withdrawal threshold using the up-down method [256]. The stimulus intensity ranged from 0.04 to 4.0 g, corresponding to filament numbers 2.44 to 4.56. The experimenter was blind to treatment group.

2.5 Isolation of prefrontal cortex, DNA capture, and bisulfite sequencing

Following completion of SAM treatment, mouse PFC was dissected following isoflurane anesthesia and decapitation. DNA methylation analysis group sizes: Sham-Sedentary: n = 4, Sham-Running: n = 3, SNI-Sedentary: n = 6, SNI-Running: n = 6. PFC was defined as a region with an anterior boundary of the frontal pole, approximately +3.00 Bregma, posterior boundary of approximately +1.00 Bregma, lateral boundaries of +1 mm from midline, and a ventral boundary wherein the olfactory bulb, caudate putamen, and

areas below the rhinal fissure and lateral ventricles were all removed [257]. This defined area isolates the prelimbic, orbital, and infralimbic cortices corresponding to the mouse medial PFC. Once dissected, tissue was homogenized and genomic DNA was extracted using the Qiagen DNeasy Blood and Tissue kit and protocol.

Genome-wide methylation analysis was performed using the Roche SeqCap Epi Developer M Enrichment system on bisulfite-treated DNA (Roche Nimblegen; WI, USA), with custom designed primers targeting promoter and enhancer regions of the genome. Probe design was based on the mm9 reference genome and associated H3K4me1 and H3K4me3 binding (probe BED file available in **Supplemental Table 1**). Briefly, 1 μg of genomic DNA per sample was fragmented into 200bp lengths, and adapter and index sequences were ligated to each end of the fragment according to the KAPA Library Preparation Kit protocol. Sample DNA was then bisulfite converted following the EZ DNA Methylation-Lightning Kit (Zymo Research; CA, USA). Sample DNA was then PCR amplified, hybridized with custom capture probes, and PCR amplified again in accordance with Roche SeqCap Epi system protocols [259]. Sample captured bisulfite-converted DNA sequencing was performed by Genome Quebec on the Illumina HiSeq 2500 following Illumina guidelines. Paired-end sequencing reads of 125bp in length were generated.

2.6 DNA methylation pre-processing

Capture sequencing data was pre-processed using the McGill University Genome Quebec Innovation Centre GenPipes Methyl-Seq Pipeline [260]. The pipeline proceeds through Trimmomatic, Bismark Align, Picard Deduplication, and Bismark Methylation Call

[261, 262]. Baseline pipeline parameters were set as a minimum sequence quality of PHRED score > 30, alignment reference genome was mm10 (GRCm38), and minimum read coverage per base was set at 10 reads. A detailed outline of the Methyl-Seq pipeline steps and process can be found at https://bitbucket.org/mugqic/genpipes. Before analysis, collected sequence data was filtered to remove a blacklist of regions identified to have anomalous, unstructured, and high signal/read counts in next gen sequencing [263]. The blacklist used was specific for mm10 and the BED file can be found in **Supplemental Table 2.**

2.7 Differential methylation analysis

Differential methylation analysis was performed using R and the MethylKit package [317]. For a CpG site to pass through to analysis, it was required to be sequenced to a minimum depth of at least 10 reads in each sample. Coverage values between samples were normalized using a scaling factor derived from differences between the median of coverage distributions. Tiling windows were used to summarize methylation information over the genome. Tiles were set to be 250 base pairs (bp) in length and advance in 125 bp steps. Methylated and unmethylated cytosine counts within each tile are summed to provide an overall methylation proportion within the tile. Only CpGs that were annotated to a promoter region, defined as 2000 bp upstream or 200 bp downstream from the transcription start site, were selected for analysis. MethylKit uses logistic regression to model a log odds ratio based on methylation proportion within each tile. Calculated p-values are adjusted to q-values using the SLIM method [318].

Tiles were defined as being differentially methylated between groups if the adjusted p-value was less than < 0.1 and had a difference in methylation $> 5\%$. While the selection of an FDR threshold of 0.1 carries greater risk of type I error, false positive, than the more typical threshold of 0.05, it is preferable for the exploratory purposes of this study. Differentially methylated tiles can be further divided into hypermethylated or hypomethylated. In comparisons between groups, the control group acts as the reference point, i.e. Control: Sham-Vehicle, Experimental: SNI-Vehicle. Therefore, if the experimental group tile methylation is 5% or larger than the control, the tile is considered to be hypermethylated, and if the treatment tile methylation is reduced by -5% or more compared to control, the tile is considered to be hypomethylated.

Tiles were annotated to their associated genes and genomic regions using the annotatePeaks function of the ChIPseeker [265] R package, using a TxDb object created from the Gencode "mmusculus_gene_ensembl" Biomart database. Each tile position was annotated and tracked individually throughout the analysis. For homology conversion, gene symbols from non-mouse species were converted to known mouse homologs based on the Mouse Genome Database (MGD) – Vertebrate Homology, Mouse Genome Informatics, The Jackson Laboratory, Bar Harbor, Maine [266].

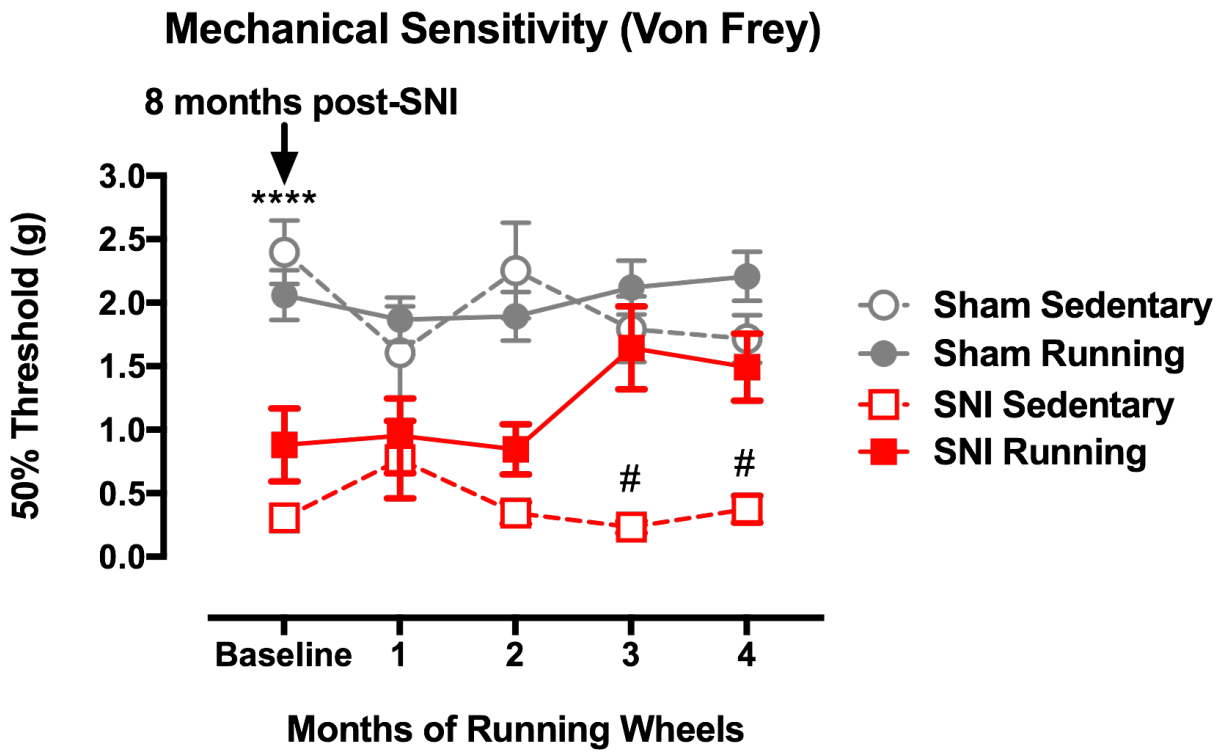
To simplify analysis of genes that undergo reversals in differential methylation after exercise intervention in SNI, we isolated genes for uniform differential methylation. Uniform differential methylation occurs when all tiles annotated to a single gene are uniformly hypermethylated or hypomethylated. Variable differential methylation occurs

when the tiles annotated to a single gene are both hypermethylated and hypomethylated tiles, and removed from reversal analysis.

2.8 Statistical analysis

Two-way repeated measures ANOVA with Bonferroni post-hoc test was used to detect group differences in mechanical sensitivity using the von Frey behavioural assay. Pairwise comparisons of tiles between experimental groups utilized logistic regression to model the log-odds ratio of methylation proportion per tile. Analyses were corrected for multiple comparisons using the SLIM method [318]. The hypergeometric test was used to test for significant enrichment of pain-related genes and for significant enrichment of gene ontology domains.

2.9 Gene ontology analysis



Differentially methylated genes identified were submitted to gProfiler [319], a web-based gene ontology tool. The GO Biological Processes and Molecular Function databases were selected as ontology databases. Ontology p-values were adjusted using the g:SCS correction for multiple comparisons [320] and an ontology was considered enriched at an adjusted p-value < 0.05. All analysed ontologies were limited to a maximum size of 2000 genes to increase function specificity. Term grouping was used to identify groups of ontologies by shared functional domains and areas using the following keywords or term names. Ions: *ions, cation, anion*; Immune: *immune, immuno-, cytokine, leukocyte, lymphocyte, bacteria, monocyte, T cell, B cell, defense, microglia, inflamm-*; Adhesion: *adhesion*; Locomotion: *locomot-, motil-, migration, -taxis*; Development and

Morphogenesis: *development, morphogenesis, -genesis, differentiation, generation, proliferation*; Cell Death: *death, apop-, necro-*; Actin Cytoskeleton: *actin, cytoskel-, supramolecular.*

3. Results

3.1 Spared Nerve Injury-induced mechanical sensitivity is attenuated by home cage running wheels.

We have previously demonstrated that SNI produces mechanical hypersensitivity at late stages of chronic pain [313]. At 8 months post-injury, animals that received SNI showed mechanical hypersensitivity in the ipsilateral hind paw compared to Sham animals (Two tailed Welch's t-test: Sham Animals (Sed + Run) vs SNI Animals (Sed + Run), $t_{39.34} = 7.04$, $p < 0.0001$) (**Figure 1**). At this time point, animals were provided with either running or control wheels. After three months, SNI and had access to running wheels reduced mechanical hypersensitivity compared to sedentary SNI mice (2-way repeated measures ANOVA, Bonferroni post-hoc: 3 month SNI-Run vs SNI-Sed, $t_{8.31} = 4.27$, $p = 0.014$; 4 month SNI-Run vs SNI-Sed, $t_{10.52} = 3.93$, $p = 0.015$). Therefore, long-term access to aerobic exercise can reduce neuropathic pain induced mechanical hypersensitivity.

[**Figure 1**: *Long-term access to home cage voluntary running wheels attenuates peripheral neuropathic pain*. 8 months post-SNI, *ad libitum* access to aerobic exercise in the form of running wheels can attenuate mechanical hypersensitivity after 3 months of exercise. Sham-Sedentary: n = 4, Sham-Running: n = 3, SNI-Sedentary: n = 6, SNI-Running: n = 6. # $p < 0.05$, SNI-Sed vs SNI-Run, 2-way repeated measures ANOVA with Bonferroni post-hoc test. **** $p < 0.0001$ Sham animals vs SNI animals, Two-tailed Welch's t-test. SNI: spared nerve injury]

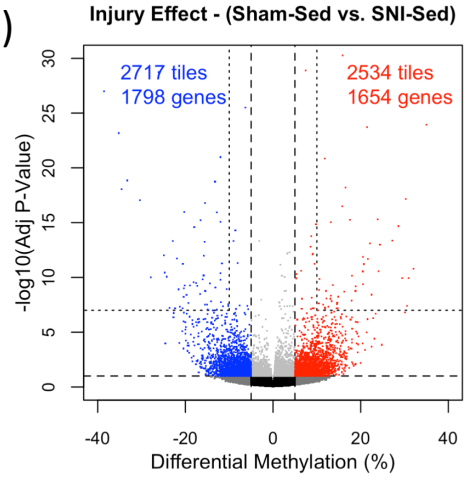
3.2 Spared Nerve Injury and Exercise lead to extensive changes in PFC DNA methylation that affect multiple functional pathways

We have previously demonstrated changes in PFC promoter region methylation in response to SNI at multiple time points post-injury [313]. Here we examined global PFC promoter methylation post-injury and post-exercise to determine the effect of exercise on injury related changes in PFC promoter methylation.

Differentially methylated (DM) regions in the PFC were identified by bisulfite capture sequencing followed by comparison between Sham-Sedentary, SNI-Sedentary, and SNI-Running conditions. Tiles of 250 base pairs (bp) were used to subdivide the genome into analysis regions, followed by selection of tiles located within promoter regions of genes defined as -2000 to +200 from the transcription start site. Genes identified as differentially methylated underwent gene ontology analysis to identify affected functional pathways. We limited the discussed gene ontology size to a maximum of 2000 genes for better specificity of affected functions and pathways.

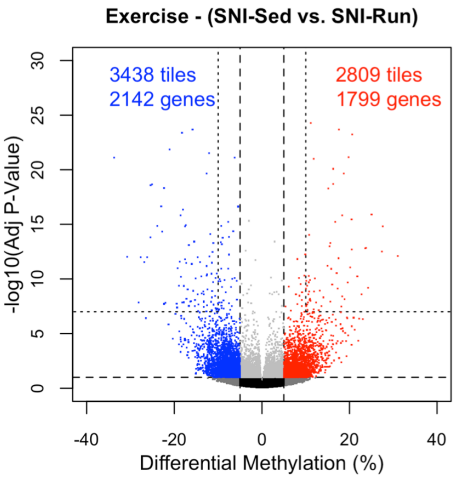
To observe the injury effect, SNI-Sedentary animals were compared against Sham-Sedentary animals 1 year post-injury and 4 months post-running wheels. We collected 203,354 tile regions covering 22,732 unique gene promoters. We identified 5251 differentially methylated tiles in total, with 2534 hypermethylated and 2717 hypomethylated, representing 1654 and 1798 unique genes respectively (**Figure 2A**). We detected a number of tiles that underwent robust differential methylation (adjusted p-value $< 1 \times 10^{-7}$ and absolute differential methylation > 10%): 56 hypermethylated tiles representing 37 unique genes, and 65 hypomethylated tiles representing 41 unique genes.

These robustly differentially methylated genes include interleukin 1 gene *Il1f8* (24.1% DM), toll-like receptor *Tlr6* (16.5% DM), and acid-sensing ion channel *Asic3* (-35.1% DM).



After submitting the identified differentially methylated genes to gProfiler, we identified 187 enriched gene ontologies in the domains of Biological Processes and Molecular Function. The top 15 enriched ontologies determined by adjusted p-value are involved in ion transport, cellular locomotion, cell morphogenesis, cell adhesion, and cytoskeletal structure (**Figure 2C**). Term grouping and hypergeometric testing was also used to identify functional domains were enriched by nerve injury. Gene ontologies related to ion transport, binding, and homeostasis were significantly enriched in Injury, with 44 related ontologies detected ($p = 3.56 \times 10^{-37}$). Other significantly enriched domains include locomotion and motility (15 ontologies detected, $p = 4.53 \times 10^{-7}$), adhesion (8 ontologies, $p = 8.79 \times 10^{-6}$), actin and cytoskeletal structure (9 ontologies, $p = 0.0034$), and cell death and apoptosis (7 ontologies, $p = 0.041$) were also detected. Morphogenesis and development (26 ontologies, $p = 0.12$) and immune and inflammation (3 ontologies, $p = 0.9$) were not significantly enriched (**Figure 2E**).

To observe the effect of exercise during neuropathic pain, we compared SNI-Running animals to SNI-Sedentary animals. We evaluated 179,769 tiling regions covering 22,338 unique gene promoters. We detected 6247 differentially methylated tiles in total, dividing into 2809 hypermethylated and 3438 hypomethylated tiles representing 1799 and 3014 unique genes respectively (**Figure 2B**). We identified 63 hypermethylated tiles and 86 hypomethylated tiles with a robust differential methylation (adjusted p-value $< 1 \times 10^{-7}$ and absolute differential methylation > 10%). These tiles represent 45 and 64 genes



respectively and include the eukaryotic translation initiation factor 3 subunit *Eif3f* (-15.2% DM), interleukin gene *Il12a* (-12.6% DM), and toll like receptor *Tlr1* (-16.3% DM).

We identified 263 gene ontologies enriched for differentially methylated genes. The top 15 ontologies are predominantly associated with locomotion and cell motility, with additional enrichments involved in areas of tissue development, morphogenesis, and biological adhesion (**Figure 2C**). Term grouping and hypergeometric analysis determined identified functional domains enriched by exercise. Exercise resulted in significant enrichment in gene ontologies related to ion transport, homeostasis, and binding (37 ontologies, $p = 5.96 \times 10^{-23}$), locomotion (24 ontologies, $p = 2.71 \times 10^{-11}$), adhesion (15 ontologies, $p = 8.08 \times 10^{-11}$), immune system and inflammation (32 ontologies, $p = 1.01 \times 10^{-8}$), and morphogenesis and development (47 ontologies, $p = 8.02 \times 10^{-4}$). Cell death (8 ontologies, $p = 0.09$) and actin cytoskeleton (5 ontologies, $p = 0.11$) were not significantly enriched (**Figure 2E**).

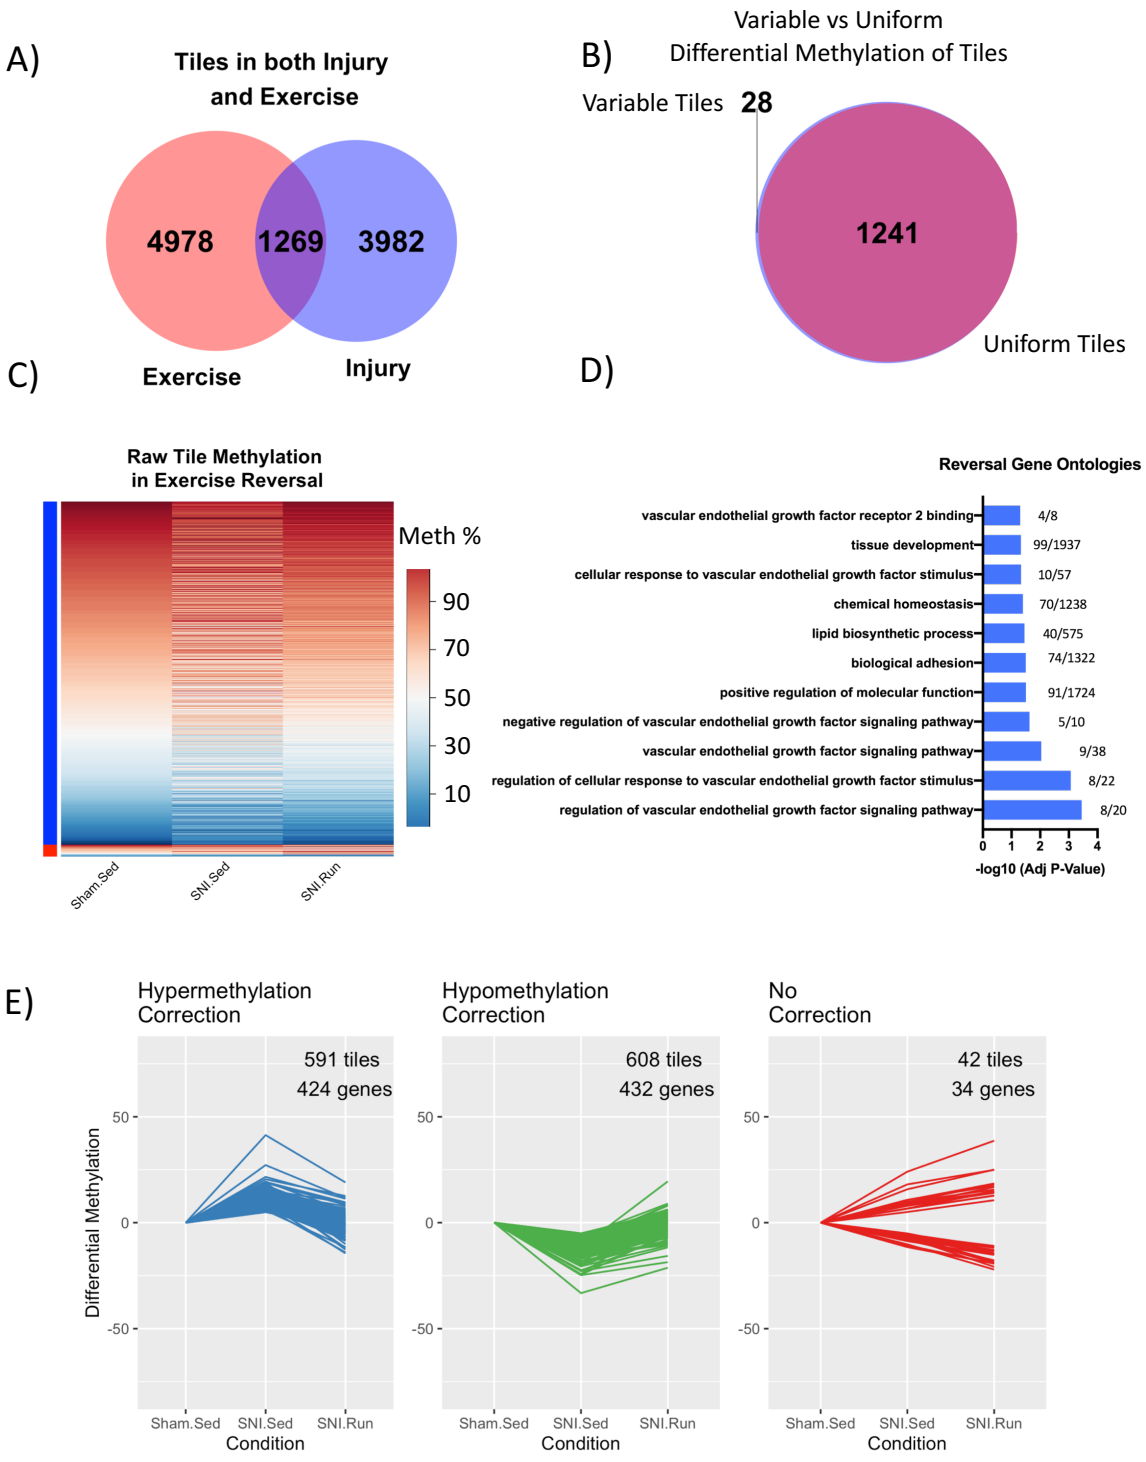
3.3 Differential Methylation after Spared Nerve Injury and exercise affect pain-related genes

To identify differentially methylated genes with known roles in pain, we compared our datasets to curated lists of pain-related genes identified by Ultsch et al [271] and the Human Pain Genetics Database (HGPD) [272]. Differentially methylated pain-related genes were significantly enriched in SNI mice, with 110 identified from Ultsch list and 49 identified from the HPGD (Ultsch: $p = 1.2 \times 10^{-6}$; HPGD: $p = 0.053$. Hypergeometric Test). In the exercise condition, differentially methylated genes were significantly enriched for only Ultsch list pain genes, with 109 DM pain genes were identified, and 49 from the HPGD (Ultsch: $p = 0.0007$; HPGD: $p = 0.298$. Hypergeometric Test). Of the 110 DM Ultsch pain genes identified in SNI and 109 DM Ultsch pain genes identified after exercise, 49 genes are shared between the two conditions. Similarly, 49 genes from SNI and 49 genes from exercise were identified from the HGPD, with 22 genes common to both SNI and exercise. A number of pain related genes displayed reversals in differential methylation after treatment, such as *Asic3*, NFkB subunit *Nfkb1*, NMDA receptor subunit *Grin2b*, glutamate metabotropic receptor Grm2, and glutamate transporter *Slc6a4* (Figure 3.



[**Figure 3**: *Spared Nerve Injury and Exercise affect pain-related gene methylation.* Differential methylation of 30 pain genes of interest where displayed differential methylation is the average of all identified tiles per gene. Pain genes have been previously identified by either Ultsch et al. 2013 [271] or the Human Pain Genetics Database [272].

3.3 Exercise reverses spared nerve injury-induced differential methylation

To further understand the impact of Injury and Exercise upon PFC DNA methylation, we identified 1269 overlapping tile regions that undergo differential methylation both after Injury and after Exercise intervention (**Figure 4A**). Filtering for uniform differential methylation identified 1241 tiles, representing 890 genes, and 28 tiles representing 10 genes that experience variable differential methylation across their promoter regions (**Figure 4B**). After selecting only uniformly differentially methylated genes, we identified 1199 tiles (856 genes) that reverse their SNI-induced differential methylation after exercise treatment, with 42 tiles (34 genes) experiencing no reversal or increases in SNI-induced differential methylation as a result of exercise intervention (**Figure 4C**). Of the 1199 reversing tiles, 591 tiles (424 genes) are initially hypermethylated as a result of Injury, and experience hypomethylation during exercise intervention, while 608 tiles (432 genes) are hypomethylated during injury and hypermethylated during Exercise (**Figure 4E**). These reversal genes are enriched in ontologies predominantly associated with vascular endothelial growth factor (VEGF) activity, as well as tissue development and biological adhesion (**Figure 4D**). Differentially methylated genes associated with VEGF signalling include *Vegfa, Rela, Il12a, Il12b, Myo1c Ptp4a3, Smoc2, Xdh, Dab2ip,* and *Cadm4*. Promoter regions that did not reverse after exercise did not associate with any gene ontology.

[**Figure 4**: *Exercise intervention results in the reversal of chronic pain induced DNA methylation*. A) 1269 tiles are differentially methylated in both Injury and Exercise. B) Of

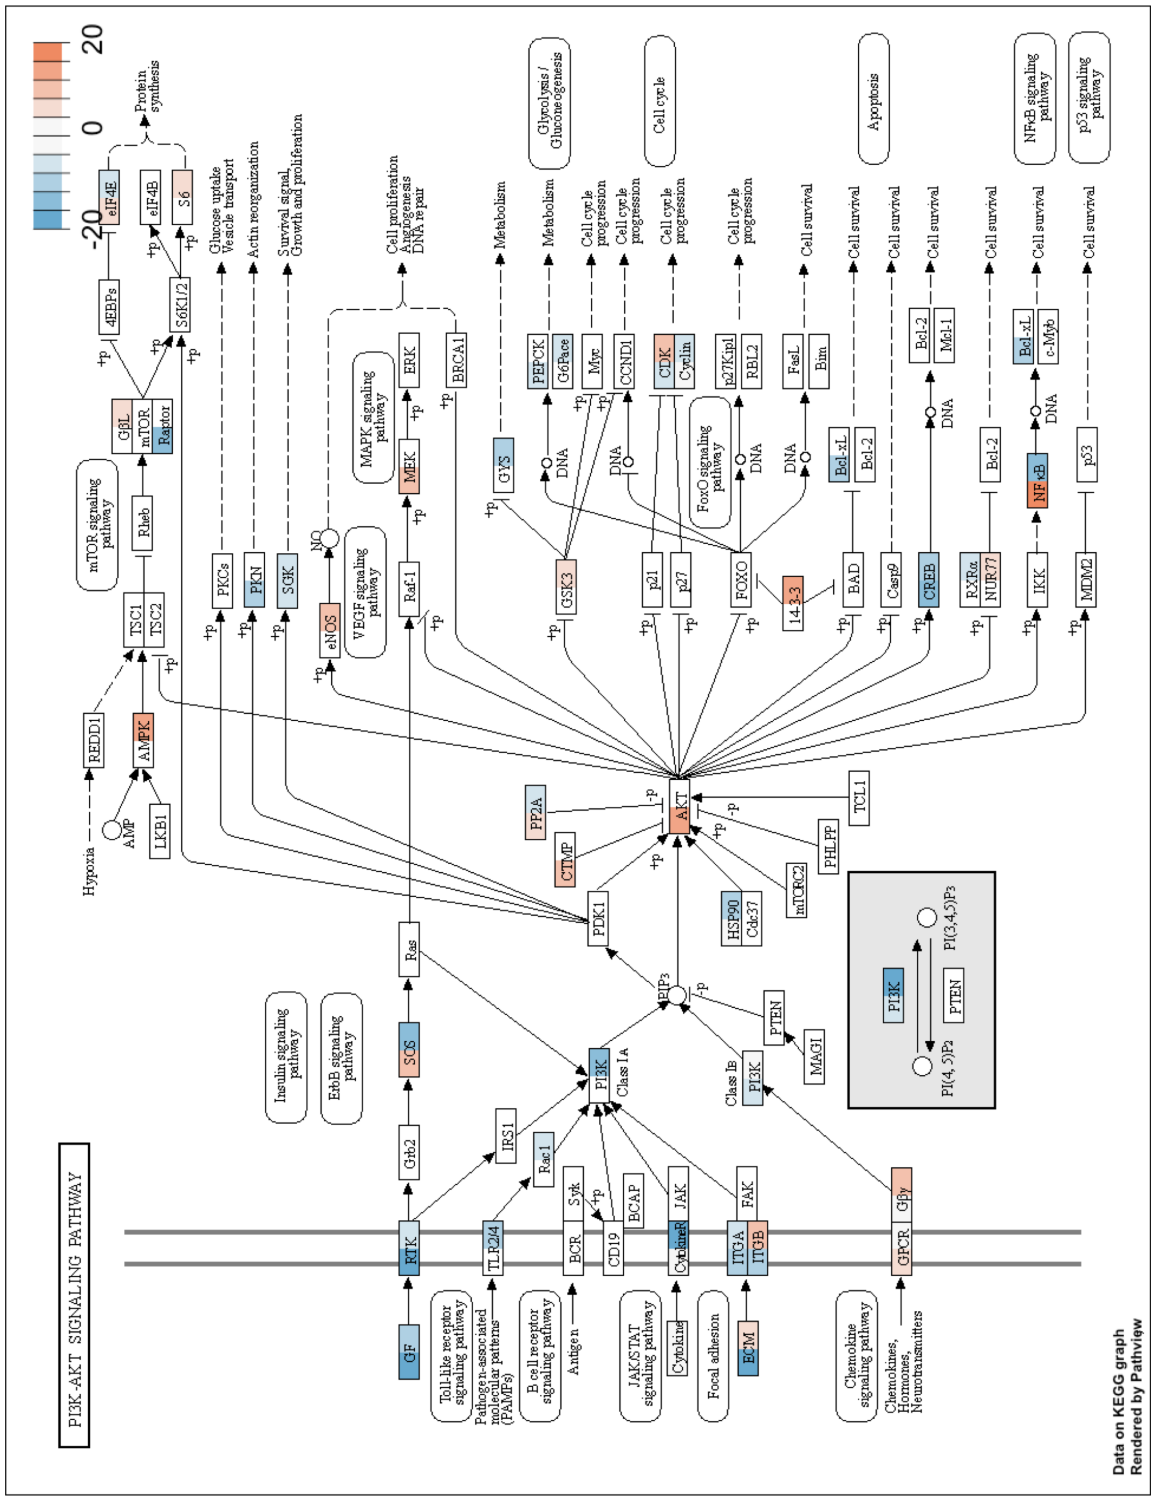
those 1269 tiles, 1241 are uniformly differentially methylated and 28 tiles show variable differential methylation. C) 1199 tiles show a reversal in differential methylation from Injury (Sham-Sed vs SNI-Sed) to Exercise intervention (SNI-Sed to SNI-Run), and 42 tiles do not undergo reversal. Side Column: Blue = reversal, red = no reversal. D) Gene ontologies associated with reversing genes. Displayed ontologies are filtered for a maximum size of 2000 genes and are from Biological Processes or Molecular Function domains. Listed are the number of differentially methylated genes / total number of genes in each ontology. E) The magnitude of differential methylation after injury, and reversal after Exercise intervention. Sham-Sedentary: n = 4, SNI-Sedentary: n = 6, SNI-Running: n = 6]

3.4 Nerve Injury and Exercise affect and reverse differential methylation at key junctions of the PI3K-Akt signalling pathway

To identify mechanisms affected by PFC DNA methylation in SNI and Exercise, we identified functional pathways that have high numbers of differentially methylated genes. From the KEGG database of biological pathways [378, 379], the PI3K-Akt signalling pathway contains 65 differentially methylated genes from Injury and 70 differentially methylated genes from Exercise, of which 26 are shared in both conditions (**Figure 5B**). 18 genes within the PI3K/Akt signalling pathway display a reversal of pain-induced differential methylation as a result of Exercise intervention.

The PI3K/AKT pathway is primarily involved in mediating neuronal survival in response to extracellular stimuli such as growth factors (GF), extracellular matrix (ECM) signalling, or response to pathogens or antigens. The PI3K/Akt pathway acts via

extracellular signals binding to receptor tyrosine kinases or G-protein coupled receptors, which stimulate phosphatidylinositol 3'-kinase (PI3K). PI3K catalyzes the production of second messenger molecule phosphatidylinositol-3,4,5-triphosphate (PIP3), which in turn subsequent activates Akt. Akt then mediates cellular functions like transcription, translation, proliferation, growth, and survival through phosphorylation of upstream substrates (**Figure 5A**).



We identified 42 extracellular signalling molecules that experience differential methylation in either Injury or Exercise: 3 cytokines, 22 ECM molecules, and 17 GFs. The receptors of these extracellular signals are also affected, with 5 cytokine receptors, 7 integrins, 5 GPCRs, 6 receptor tyrosine kinases and the toll like receptor *Tlr4* experiencing differential methylation. A number of extracellular signals and their paired receptors were affected, including vascular endothelial growth factor *Vegfa*, fibroblast growth factors *Fgf7*, *Fgf8* and their receptors *Fgfr2*, *Fgfr3 [380],* neurotrophin *Ntf3* and its receptor *Ntrk2*, macrophage colony stimulating factor *Csf1* and *Csf1r*, granulocyte colony stimulating factor *Csf3* and *Csf3r*, and many collagens, fibronectins, and laminins which bind to integrins (ITGA and ITGB) (**Figure 5C**).

Downstream of the cell membrane receptors, intracellular signalling molecules activate PI3K. Integrins, cytokine receptors, RTKs, and TLRs send their downstream mediators FAK, JAK, Rac1, and IRS1 respectively to activate class IA PI3Ks, while GPCRs send $G\beta\gamma$ complex proteins to activate class IB PI3Ks. In our dataset, only the class IA PI3K gene *Pik3cd* was hypomethylated by exercise, along with its upstream regulator *Rac1*. The class IB PI3K stream was more heavily affected, with the only known

class IB PI3K *Pik3cg* and its two regulatory subunits *Pik3r5* and *Pik3r6* all experiencing differential methylation, as well as 5 different Gβγ complex genes (**Figure 5C**). Both class IA and IB PI3Ks catalyze the formation of PIP_3 which in turn serves to activate Akt, the main mediator of this pathway. The Akt gene *Akt2* is hypermethylated after Injury, and a number of its regulatory mediators are also affected in Injury and Exercise, including Akt repressor PP2A subunits *Ppp2r2d* and *Ppp2r3a*.

Finally, the phosphorylation of Akt triggers the activation of downstream pathways involved in cellular survival, metabolism, cell cycle progression, metabolism, and protein synthesis. A number of crucial mediators of cellular survival are differentially methylated, including the CREB genes *Creb5* and *Atf6b*, and the NFκB genes *Nfkb1* and *Rela* (**Figure 5C**). The anti-apoptotic gene *Bcl2l1* is also hypomethylated in response to injury. In cell cycle regulation, CDK genes *Cdk4* and *Cdk6* along with their cyclin regulators *Ccnd2* and *Ccnd3* are differentially methylated. Also, interesting to note are the differentially methylated genes in the mTOR signalling pathway. Two subunits of the mTOR complex, *Raptor* and *Mlst8*, are differentially methylated as well as the downstream targets of the mTOR complex, eukaryotic initiation factors *Eif4e* and *Eif4e2*, and ribosomal protein *Rps6*.

4. Discussion

Given the difficulty of developing novel pharmacological interventions and the complexity and diversity of chronic pain-related mechanisms, our study sought to explore other therapeutic avenues and identify their impact upon PFC functioning. Increased physical activity is commonly recommended and prescribed for chronic pain amongst clinicians and physiotherapists, with demonstrated efficacy in ameliorating reported pain. While previous work shows aerobic exercise can induce epigenetic changes and attenuate grey matter loss, there has yet to be any work exploring the effects of aerobic exercise on PFC DNA methylation in subjects with long-term chronic pain. Our study provides evidence that aerobic exercise induces epigenetic changes in PFC during chronic pain, affecting a number of functional pathways and reversing hundreds of pain-related changes in DNA methylation.

Here we demonstrate that non-pharmacological therapeutic intervention can attenuate long-term peripheral neuropathic pain and mediate epigenetic changes in PFC. First, by providing SNI animals access to voluntary running exercise, we can attenuate mechanical hypersensitivity 8 months after onset of neuropathic pain. These results are in line with previous findings from human and animal studies [136, 381]. Second, we show that voluntary exercise can alter PFC promoter DNA methylation of thousands of genes after animals have experienced a long-term neuropathic pain. This is the first study to demonstrate genome-wide changes in PFC methylation after exercise, and is supported by work in hippocampus or on single genes [382, 383]. Third, these changes occur in a number of pain-relevant functional domains such as ion transport and homeostasis, immune functioning, and cytoskeletal structure. Finally, many of these exercise-related changes reverse the effects of chronic peripheral injury on DNA methylation. This implies that treatment reverses disease pathology at the epigenetic level and is supported by other work examining addiction and post-traumatic stress [322, 323]. Finally, the PI3K-Akt signalling pathway is heavily affected by injury and exercise, with many downstream implications for cellular survival, neurogenesis, learning and memory, and protein expression.

4.1 PFC DNA Methylation in Response to Injury and Exercise

PFC DNA methylation is dramatically altered after long-term neuropathic pain and treatment of that pain with increased physical activity. At one year post-injury, we identified over 5000 differentially methylated regions affecting nearly 3500 genes, representing a substantial portion of the genome undergoing some degree of altered

methylation. Even isolating for genes that undergo a substantial change with an adjusted p-value of $< 1x10^{-7}$ and absolute differential methylation > 10%, we still identified over 70 genes that show a strong change as a result of injury. This result is mirrored after the exercise intervention, with nearly 6500 differentially methylated tiles representing almost 4000 genes, and over 100 genes going through robust differential methylation. While some of these widespread alterations in DNA methylation may not translate to meaningful changes in gene expression, a substantial proportion of the genome has been impacted by and is responsive to long-term injury and its therapeutic intervention.

To determine what molecular and cellular functions may be regulated by DNA methylation, we turned to gene ontology analysis. We identified a number of broad functional domains that were affected by injury or exercise or both, such as ion transport and homeostasis, cellular adhesion, locomotion and motility, and immune function. These broad functional domains were identified by grouping gene ontologies by similar function.

Ontologies related to ion transport, homeostasis, and binding were heavily enriched in both injury and exercise ontologies, with 44 and 39 ontologies detected respectively, and accounting for 8 of the top 15 gene ontologies in Injury. Ontologies related to calcium ion transport and homeostasis genes were affected in particular by injury and exercise. A number of genes involved in regulating Ca^{2+} concentration and activity are differentially methylated, potentially affecting their expression and the regulation of Ca^{2+} in the cortex. The influx and homeostasis of Ca^{2+} is crucial for triggering neurotransmitter release, mediating synaptic plasticity, and controlling cell survival and apoptosis [384-386]. In DRG sensory neurons, peripheral neuropathy reduced cytosolic

concentrations of Ca^{2+} [387, 388] and caused a loss of inward Ca^{2+} current, in particular through T-type Ca^{2+} channels [389, 390], which lead to increased neuronal hyperexcitability. In SNI mice, cytosolic Ca^{2+} concentration is potentially reduced after the hypomethylation and subsequent increased expression of calcium pump SERCA (*Atp2a3*), which moves calcium from cytosol into the ER, and the hypermethylation of the sodium/calcium exchanger *Slc8a2*, which moves calcium out of the mitochondria into the cytosol. Calcium influx through T-Type calcium ion channel *Cacna1g* may also be reduced as a result of hypermethylation in injury. Conversely, exercise may increase cytosolic Ca^{2+} concentration by increasing expression of ER Ca^{2+} exporters: IP3 receptors (*Itpr1, Itpr2*) and ryanodine receptor (*Ryr2*), all of which are hypomethylated in the exercise group. *Slc8a2* also reverses its differential methylation and becomes hypomethylated, potentially increasing the export of Ca^{2+} from the mitochondria. Finally, the T-type calcium channel *Cacna1g* also reverses to hypomethylation, potentially increasing influx of calcium. Interestingly, restoring inward Ca^{2+} current reduced neuronal hyperexcitability [391]. Changes of internal calcium concentration and calcium influx can also affect long term potentiation (LTP) and synaptic plasticity.

Synaptic plasticity is a hallmark of chronic pain, with changes in glutamate transmission and cortical excitation noted amongst chronic pain patients and experimental models [51, 392]. LTP proceeds through an early transient phase mediated by PKC and CaMKII and the insertion of new AMPARs into the post-synaptic membrane, and a late persistent phase involving the growth of a new dendritic spine mediated by the MAPK signalling pathway. First, multiple NMDA receptor subunits (*Grin2b, Grin2c, Grin2d*)

that are required for the calcium influx to initiate LTP are hypermethylated in injury and hypomethylated in exercise. The key early LTP genes CaMKII (*Camk2a*) and calmodulins 1 and 2 (*Calm1, Calm2*) are hypermethylated by both injury and exercise. Therefore, early phase LTP may be repressed in both conditions. However, late phase LTP may be repressed in injury and promoted by exercise. PKCζ (*Prkcz*), required for late phase maintenance, and the synaptic structure mediator *Rac1* are both hypomethylated by exercise. Rac1 is essential for regulating synaptic growth and plasticity and Rac1 inhibition induces significant deficits in LTP and can reduce neuropathic pain 1 month after injury [276, 393]. An interesting future direction would be to explore if the hypomethylated Rac1 observed was to promote LTP as an adaptive response to exercise, causing the attenuation of pain. These observations concur with previous work showing exercise induces changes in mRNA expression of genes associated with neuronal activity, synaptic structure, and plasticity [394].

Further work is needed to explore the relationship of DNA methylation and calcium regulation as a number of other Ca^{2+} ion channels (*Cacna1s, Cacna1d, Cacna1a, P2rx1, P2rx2, P2rx3, P2rx7*), Ca^{2+} transporters (*Atp2b1, Slc25a4*), and Ca^{2+} mediators (*Stim1, Orai3, Adcy3, Adcy7, Adcy8*) are also differentially methylated in injury and exercise. Other studies have shown interactions between nuclear calcium signalling and histone deacetylase activity [395, 396] and this interplay may help mediate DNA methylation responses to chronic pain.

Another functional domain that was regulated by both injury and exercise was immune response and inflammation. Interestingly, only 3 immune related gene ontologies were detected in injury, while 32 immune related gene ontologies were detected in exercise. Immune and inflammation ontologies in exercise were also predominantly hypomethylated, potentially indicating the activation and increased expression of immune related genes and domains in exercise. Chronic exercise is already known to counteract chronic inflammation in the brain by decreasing pro-inflammatory M1 microglia and the expression of proinflammatory cytokines [397, 398]. Here, chronic exercise may be increasing anti-inflammatory responses in PFC by upregulating production of anti-inflammatory cytokines and promoting M2 microglia proliferation and migration to the PFC. Indeed, the M2 microglia inducing *Il4* was hypomethylated by exercise along with the M2 microglia secreted anti-inflammatory *Ccl22*. Despite these anti-inflammatory indicators, the immune response of the brain after injury and exercise is not clear. A number of pro-inflammatory interleukins (*Il1f6, Il12a, Il12b, Il17f, Il20*) are hypomethylated by exercise indicating a pro-inflammatory response. Both Injury and Exercise comparisons show an enrichment of locomotion and cell adhesion ontologies potentially representing the invasion and activation of microglia. Given the involvement of immune factors in multiple systems and the existence of microglia on a pro-inflammatory and anti-inflammatory continuum, the contribution of inflammatory processes to the therapeutic benefits of exercise against late-stage chronic pain is complex and requires further investigation.

4.2 PFC Methylation Reversal after Exercise

Environmental and external factors are capable of affecting cortical DNA methylation and this methylation is plastic, with a number of studies successfully reversing disease or condition related DNA methylation after intervention [322, 323, 349]. We are the first study to investigate the effect of exercise on chronic pain-induced changes in DNA methylation, and we demonstrate not only widespread changes after exercise but also the reversal of chronic pain related DNA methylation at hundreds of positions. We identified 1269 differentially methylated regions that are shared between injury and exercise, of which 1199 undergo a reversal in differential methylation. Said differently, nearly 20% of differentially methylated genes identified in injury reverse their differential methylation after an exercise intervention that successfully attenuated pain.

How this reversal occurs is still unknown, however any widespread changes in DNA methylation must come about through the activity of methylating DNMTs, demethylating TET enzymes, and the appropriate histone modifications that ensure the same genetic regions are available to be modified. Previous work has found decreases in DNMT expression and histone deacetylase (HDAC) activity and increases in histone acetylase (HAT) in hippocampus and frontal cortex after treadmill or running wheel [374, 399, 400]. Swimming also increased H3K9 and H3K14 acetylation in hippocampus of mice, both strong histone markers of active promoters [401, 402]. Decreases in DNMT and HDAC activity combined with an increase in histone acetylation and HAT activity would favour demethylation and an open chromatin environment, implying that the genome is in a state of plasticity and methylation changes can more readily occur.

However even though the genome may be in an open state, one of the key questions that must be answered is how specific genes and sequences are targeted for differential methylation and why certain sequences are available for reversal while others are resistant to intervention.

4.3 Impact of Injury and Exercise on PI3K-Akt Pathway

For a closer examination of one of the affected signalling pathways in injury and exercise, we selected the PI3K-Akt pathway. Increased expression and phosphorylation of PI3K and Akt in dorsal root ganglia and spinal cord is associated with increased pain sensation, and the inhibition of PI3K successfully reduces pain [403, 404]. PI3K/Akt signalling contributes to central sensitization in the spinal cord, mediates microglia and astrocyte reactivity, and regulates neuronal survival [405-408]. In our dataset, the class IA PI3Kδ (*Pik3cd*) is hypomethylated in exercise. The class IA PI3Ks are primarily activated by upstream receptor tyrosine kinases and growth factors. In particular, the growth factor VEGF (*Vegfa*) was hypermethylated in injury and hypomethylated in exercise, and VEGF related ontologies were significantly enriched among reversal genes. VEGF activity via PI3K signalling increases neurogenesis and induces synaptic remodelling through regulation of NMDA receptor 2B subunits (*Grin2b*), which is hypomethylated in exercise as well [409, 410]. Increased expression of VEGF is also responsible for promoting angiogenesis, hypothesized to improve cognition and brain health through increased perfusion [411, 412]. Downstream of VEGF and PI3K, two forms of the small GTPase Rac (*Rac1, Rac2*) were also hypomethylated in exercise. Rac signalling induces vascular permeability and is required for the stabilization of actin

filaments during LTP synapse formation [413, 414]. Thus in exercise, VEGF may mediate a pro-recovery response through the PI3K/Akt pathway, resulting in novel synaptic plasticity, angiogenesis and the potential invasion of circulating immune cells resulting in PFC signalling undergoing pain attenuating adaptation. The differential methylation of these genes may reflect a more persistent change in expression and a transition to a new brain state.

4.4 Limitations

A number of limitations must be considered regarding our results and conclusions. First, our results require further validation and follow up studies to examine the downstream impact of the differential methylation observed. While promoter region methylation is a strong regulatory mechanism of gene expression, other mechanisms can influence gene transcription, translation, and ultimately expression. Second, given our group sizes of 3-6 and a permissive adjusted p-value of 0.1, there is a greater risk of false positives. The permissive adjusted p-value was selected in order to maximize the sensitivity of our analysis, in line with the exploratory nature of our study. Third, our study focused on promoter region methylation, however non-promoter DNA methylation can also have impacts upon gene transcription with methylation at distal enhancers and within the gene body capable of regulating gene transcription [183, 295, 351]. Fourth, we were unable to validate that each mouse in our running paradigm ran the same amount and therefore received the same "dosage" of exercise. We wished to avoid potential confounds of forced running paradigms, such as stress-induced analgesia, in favour of voluntary and *ad libitum* exercise. Fifth, our study contained male animals only therefore

our conclusions do not account for sex differences in response to chronic pain. We recognize these limitations but we also believe our results provide novel and relevant insight to PFC DNA methylation response during chronic pain and its successful treatment.

5. Conclusions

Our findings provide first evidence for reversal of chronic pain-induced epigenome-wide changes in DNA methylation as a result of therapeutic exercise. The widespread involvement of differentially methylated gene involved in calcium signalling, LTP, and immune responses in the PFC may provide new insights to how these processes are regulated in response to injury and recovery. While the responsiveness of DNA methylation to intervention is well-established, we also demonstrate that exercise can reverse DNA methylation on a large scale after long-term chronic pain. This implicates DNA methylation as a contributor to the cortical recovery observed in human patients after successful therapeutic intervention. These findings are a promising insight to the responsiveness of prefrontal cortex to non-pharmacological intervention, and a foundation for further research into more effective treatments against chronic pain.

Chapter 5: Conclusions

6.1. Summary

Chronic pain is a leading cause of disability and reduced quality of life, and remains a difficult disease to treat and manage. This thesis explored the contribution of DNA methylation as a regulatory mechanism in maintaining chronic pain and in mediating therapeutic interventions. We hypothesized that PFC DNA methylation would undergo significant changes in response to both chronic pain onset and to successful pain reducing therapies.

Our first study characterized the progression of DNA methylation changes in the brain at four time points along chronic pain development and maintenance. We found robust differential methylation of hundreds of genes at one day, two weeks, six months, and one year post-injury. This study was the first to show rapid changes in PFC DNA methylation one day after injury and the first to explore PFC DNA methylation one year after injury. Moreover, differentially methylated genes displayed time dependent dynamic patterns of methylation across the time course, with many pain related genes only being differentially methylated at specific time points. This work demonstrated that peripheral neuropathic pain induces changes in PFC DNA methylation that evolve as pain becomes increasingly chronic.

Having identified a clear and dynamic relationship between DNA methylation and chronic pain, we investigated PFC DNA methylation response to interventions. We previously demonstrated chronic systemic SAM administration attenuates chronic pain [234]. Our second study examined the effect of this successful intervention upon PFC

DNA methylation. Chronic SAM administration induced widespread differential methylation and we identified potential underlying mechanisms contributing to SAM's action in alleviating chronic pain.

Following pre-clinical evidence and clinical reports [136], we next investigated the efficacy of voluntary exercise in reducing chronic pain. We confirmed that voluntary running exercise successfully attenuates chronic pain and demonstrate widespread changes in DNA methylation. This successful intervention one year after injury is the first to explore PFC DNA methylation response to and recovery from chronic pain at such a late time point. This work contributes to a rapidly growing literature on the relationship of epigenetics, exercise, and chronic pain and is the first to investigate PFC DNA methylation in a successful exercise-based intervention.

The results of our two intervention studies demonstrate that successfully attenuating pain is reflected in the PFC methylation state through a reversal of pain-related differential methylation. The direct reversal in DNA methylation of a subpopulation of genes after reduction of a disease state has been demonstrated in other fields, however this is the first evidence in the field of chronic pain.

6.2. Discussion

Exploring PFC DNA methylation in response to chronic pain provides two forms of insight: first, by revealing an important regulatory process mediating the functional and structural changes seen in PFC during chronic pain, and second, by identifying functional pathways and domains affected by chronic pain.

Previous research provided an excellent foundation for the DNA methylation changes we could expect in response to chronic pain. Nearly all experiments examining DNA methylation in pain-related structures during chronic pain clearly show widespread changes. These changes are observed to occur rapidly [235, 236], but are also maintained during later stages of chronic pain [200].

6.2.1. **Dynamics of PFC DNA Hypermethylation and Hypomethylation**

The results from all three experiments within this thesis clearly describe malleable, responsive, and dynamic changes in DNA methylation as chronic pain develops, consolidates, and is treated. Our time course study revealed differential methylation at every time point. Differential PFC methylation was skewed towards hypermethylation at each time point and in the SAM study control group, a result that has been noted in previous studies [236]. This hypermethylation presents an interesting contrast to our previous research, with PFC hypomethylation observed using the same pain model at similar time points [233, 234]. This discrepancy can be explained by the difference in techniques and is revealing about the response of PFC DNA methylation. Gregoire et al. 2016 and Tajerian et al. 2013 measured global methylation using methods that do not account for genomic location [233, 234]. In contrast, our analysis was targeted and limited to gene promoter regions, thus implying chronic pain induces a global hypomethylation with site-specific hypermethylation. This dual profile of methylation changes is a common hallmark in cancer, with site-specific hypermethylation of tumor suppressor genes and hypomethylation of centromeric repeated elements or long and short interspersed repeat

elements (LINE or SINE) [415-417]. Moreover, the specific genes and repeated elements that are differentially methylated vary depending on the cancer subtype, implying a functional role for both in cancer development [418].

The global hypomethylation observed in cancer predominantly occurs at centromeric satellite DNA, LINEs, and SINEs. Hypomethylation in these regions lead to chromatin instability as large segments of heterochromatin are demethylated and released from being sequestered at the nuclear membrane. In cancer, this results in increased risk of DNA strand breakage and recombination events. The disruption of chromatin structure also interferes with enhancer-promoter interaction and can move actively transcribed genes to the nuclear periphery resulting in their repression [419]. Another proposed effect of centromeric hypomethylation is the release of sequestered DNMTs and MBDs that were engaged in repressing these non-coding regions [418]. The release of DNMTs and MBDs would induce widespread hypermethylation at available sites throughout the genome. These mechanisms are currently only hypothesised to occur in chronic pain, however the similarity of global hypomethylation between cancer and chronic pain encourages further investigation.

In contrast to global hypomethylation, hypermethylation in cancer almost universally targets CpG islands. Cancer-related hypermethylation has characteristic profiles associated with the specific cancer subtypes and has a high concordance with genetic alterations, disease risk, and outcomes [420]. It is unclear if this characteristic profile is causal or simply correlated, however these profiles are most likely the result of a specific mechanism or environmental cue that causes their development. Cancer

research has observed that hypermethylated regions are associated a simultaneous facultative heterochromatin histone mark, H3K27me3 [421-423], and active promoter mark, H3K4me3 [424, 425]. The combination of the repressive H3K27me3 and active H3K4me3 marks is known as a bivalent promoter or poised promoter. They are common during development as genes in embryonic stem cells await the appropriate environmental signal to initiate transcription. However, it has been recently proposed that bivalent domains may also exist in adult tissues as a mechanism to tightly regulate tissue specific genes [426, 427] as the conversion of H3K27me3 to H3K27 acetylation serves to activate promoters [428]. Indeed, the hypermethylation of bivalent promoters has also been observed as blood, brain, kidney, and skeletal muscle tissue ages [429, 430].

Pain-related hypermethylation could be targeted in chronic pain via a similar bivalent promoter-based mechanism. EZH2 is the HMT responsible for methylating and marking H3K27 methylation as part of the Polycomb repressive complexes 2 and 3 [431]. EZH2 is also required for DNMT binding and DNA methylation at EZH2-targeted promoters [432]. EZH2 is elevated in spinal cord after peripheral nerve injury in both neurons and microglia and when EZH2 activity is inhibited, thermal and mechanical hyperalgesia are attenuated [433]. Thus pain-related hypermethylation may be mediated by EZH2-bound DNMT directed towards H3K27me3 marked gene promoters. Hypermethylation at H3K27me3 marked gene promoters may push these promoters to a more repressed epigenetic state, leading to cellular dysfunction or abnormal function. This mechanism may be particularly relevant in sustaining microglial inflammatory states. EZH2 expression is much higher in microglia than in neurons during chronic pain [433],

and EZH2 H3K27 methylating activity promotes a pro-inflammatory M1 phenotype and represses an anti-inflammatory M2 phenotype [434].

Finally, while we noted a predominant skew towards hypermethylated genes, we must also address the significant number of hypomethylated genes observed at all time points during the chronic pain time course. In contrast to the relationship between hypermethylation and bivalent promoters in cancer and aging, hypomethylation is associated with a number of different histone marks. In cancer, hypomethylation is observed at the constitutive heterochromatin H3K9me3 marks, perhaps in correlation to the global hypomethylation at centromeres discussed above. In contrast, hypomethylation in aging occurs in a tissue dependent manner, primarily at the active enhancer mark of H3K4me1 but can also occur at H3K4me3 marks. The site selection for hypomethylation in aging appears to be closely related to transcription factor binding [435]. Given that we detected hypomethylation in promoter regions in our studies, it is unlikely that hypomethylation in chronic pain follows a cancer-like mechanism and may be similarly dependent on transcription factor targeting. Transcription factors are known to prevent *de novo* DNA methylation by sterically interfering with DNMT binding and by recruitment of TETs [436-438]. Thus, hypomethylation in chronic pain may be guided by transcription factor binding at gene promoter regions. Further research is required to match hypomethylated pain-related promoters with transcription factor binding sites and histone marks, and determine the mechanism of hypomethylation targeting in chronic pain.

In summary, three mechanisms of differential methylation may explain the methylation profiles observed in chronic pain. The hypermethylation and hypomethylation seen at each time point might be the result of time point specific profiles of vulnerable or available DNA regions. Pain-related hypermethylation may be targeted by bivalent promoters in the PFC, with tissue specific profiles dictating which genes are affected. Pain-related hypomethylation may occur via transcription factor binding to prevent methylation in response to chronic pain or by actively promoting demethylation via recruitment of TET, again with tissue specific binding patterns dictating affected genes. Centromeric hypomethylation may contribute to cellular dysregulation by disrupting enhancer-promoter interactions and inappropriately repressing genes. It is likely that much of the observed differential methylation is irrelevant to actually mediating chronic pain changes. Many of the changes may be non-specific, non-targeted collateral effects of the reaction to chronic pain. Similar dynamics are seen in cancer and development [418, 439].

6.2.2. **Impact of PFC DNA Methylation on Synaptic Plasticity**

Our studies reveal widespread changes in DNA methylation during the time course of chronic pain development and in response to intervention. As mentioned during the introduction, most forms of chronic pain present with synaptic plasticity in the form of peripheral or central sensitization. Among our studies, functional domains related to the actin cytoskeleton and ion channels and transport are particularly enriched for differentially methylated genes and are related to synaptic plasticity. The involvement of

DNA methylation in these functions may imply an overarching mechanism regulating multiple cellular systems at once, and a potential therapeutic avenue to simultaneously target multiple dysregulated systems.

Synaptic plasticity is one of the predominant proposed mechanisms that mediate chronic pain in PFC. Indeed, previous research has observed changes in synaptic formation and density, neurotransmitter production and release, and post-synaptic receptors [350, 440, 441]. These processes are affected by differentially methylated pathways throughout the chronic pain time course and during interventions.

Actin and cytoskeleton formation, organization, and regulation are some of the key elements that regulate synaptic formation and density. Actin formation and stabilization is a dynamically regulated process that requires frequent expression of necessary proteins. The regulation of actin assembly and stabilization is crucial in both LTP and long term depression (LTD), and affects the growth or loss of dendritic synapses [442]. The Ras and PI3K signalling pathways are involved in mediating synaptic structure and trafficking of AMPA receptors and both hyper- or hypoactivity of these signalling pathways impairs synaptic plasticity [443]. The actin cytoskeleton is relevant during chronic pain, as a foundation for synaptic plasticity but also to mediate intracellular signalling cascades [275, 298, 444]. Across the chronic pain time course, gene ontologies for the actin cytoskeleton are enriched for differentially methylated genes, potentially reflecting a dysregulation of normal cellular architecture as chronic pain develops. The Ras and PI3K-Akt signalling pathways are differentially methylated during chronic pain and undergo reversals after intervention. Differential methylation of these pathways could result in the abnormal

regulation and expression of the actin cytoskeleton and affect normal synaptic transmission.

In addition to the actin cytoskeleton, the glutamatergic AMPA and NMDA receptors are also differentially methylated. AMPA and NMDA receptors are a crucial element in synaptic plasticity, required for the influx of calcium that triggers either LTP or LTD [445]. Both receptors have a well-characterized role in chronic pain and have been previously investigated as analgesic targets [446-448]. AMPA receptor subunits *Gria2* and *Gria1* are hypermethylated at 6 months post-injury and in the injury group of the SAM experiment respectively. NMDA receptor subunits are differentially methylated at 6 months post-injury and following both SAM and exercise interventions. Specifically, the NMDA receptor subunit *Grin1* is hypomethylated 6 months post-injury, while *Grin2b, Grin2c,* and *Grin2d* were all hypermethylated after injury and hypomethylated after intervention in the intervention studies. This methylation profile of AMPA and NMDA receptors may indicate a preference for LTD in the PFC during the later stages of chronic pain. LTP and LTD rely on similar molecular mechanisms but differ through the amplitude of pre-synaptic signalling and post-synaptic potentials. High frequency or high amplitude pre-synaptic glutamate release that induces large excitatory post-synaptic potentials favour LTP, while low frequency but prolonged glutamate release that results in modest post-synaptic depolarization favours LTD [445]. Hypermethylation of AMPA and NMDA receptor subunits would imply reduced expression, potentially indicating smaller excitatory post-synaptic potentials after injury. Subsequent hypomethylation of NMDA receptor subunits after intervention may indicate increased expression of NMDA receptors and promotion

of LTP. Increased LTP could contribute to the increase in cortical grey matter observed in human patients after successful pain attenuation.

Changes in synapse signalling and structure are well-established responses to chronic pain occurring at every level of pain transmission. Targeting DNA methylation is a novel potential therapeutic approach to reversing maladaptive changes in these functions during chronic pain. The reversal of injury-induced changes in DNA methylation by both a pharmacological and a non-pharmacological intervention, long after the establishment of chronic pain, support this conclusion.

6.2.3. **Limitations**

When considering the results of this thesis and their implications for pain research, a number of limitations must be kept in mind. First, across all three experiments only male mice were used to explore the relationship between PFC DNA methylation and chronic pain. Sexual dimorphism in pain sensitivity has been well established in both human populations and animal models. Pain is more frequently reported by women than men, and several common chronic pain conditions are more prevalent in women [449]. There is also evidence for morphine to be moderately more efficacious in women than men in clinical and experimental studies, though the evidence is less clear for other μ-opioid and κ-opioid receptor acting compounds [450].

Animal models of chronic pain have also revealed robust sex differences in pain sensitivity and biological response with female mice showing greater pain behaviour than their male counterparts [451, 452]. Differences in immune cell activity have been proposed to mediate some proportion of the observed dimorphism [294, 453, 454]. Of

particular relevance to this thesis, a study of mouse medial PFC in SNI found a greater deficit in cognitive flexibility coupled with a loss of parvalbumin expression and decrease in axon initial segment length in layer 5/6 of the infralimbic cortex in males. In contrast, female mice had less impairment and no changes in parvalbumin expression or axon initial segment length [115]. This difference in behaviour and cellular response highlights the clear sexual dimorphism in pain sensitivity and pathobiology between males and females. By collecting only male PFC, the data we present here represents the male PFC DNA methylation response with associated functional domains. However, there are likely to be female specific differential methylation that must be examined to fully understand the relationship between PFC DNA methylation and chronic pain.

Another limitation of this thesis is the use of only one pain model across all three manuscripts. The spared nerve injury model of neuropathic pain produces a persistent and robust peripheral neuropathy, which was preferable to ensure a reliable and consistent pain presentation across all test animals. However, this model does not reflect the clinical presentation or prevalence of chronic pain disorders observed in human populations. In human pain populations, individuals presenting with neuropathic characteristics represent ~20% of all chronic pain sufferers [455-457], and direct nerve damage only accounts for 4% of reported chronic pain [7]. By contrast, rheumatoid and osteoarthritis account for nearly 40% of reported chronic pain, with herniated and deteriorating discs representing an additional 15%. While these conditions underlie the vast majority of chronic pain, their complexity is not represented by our model.

A number of animal models exist to model these more common causes of chronic pain. To model arthritic chronic pain, intra-articular injection of collagen antibodies, collagen, or adjuvants such as Complete Freund's Adjuvant will generally produce an inflammatory response and pain behaviours for 1-2 weeks [458]. Models of discogenic back pain commonly consist of traumatic puncture or damage to lumbar discs, or transgenic knockout induced disc degeneration such as SPARC-null mice [459]. However traumatic puncture of the disc does not always result in discogenic pain, and the transgenic knockout of the SPARC gene could have unforeseen effects upon genetic or epigenetic regulation. Thus, while other pain models may have greater clinical validity and relevance, the SNI model was chosen to produce a reliable and consistent chronic pain phenotype to evaluate PFC DNA methylation across subjects.

6.3. Future Directions

There are a number of questions that require additional investigation to further the work accomplished in this thesis.

1. *To what extent do the observed changes in DNA methylation translate into changes in gene transcription and protein expression?*

There is a clear impact of chronic pain upon PFC DNA methylation. However, previous research has demonstrated that not all changes in DNA methylation translate into meaningful changes in gene transcription and protein expression. Performing follow up RNA-sequencing on the same tissue from which this dataset was derived will help connect DNA methylation changes to potential changes in phenotype. Measurement of

protein expression will provide further insights into the functional outcome of altered DNA methylation.

2. *Which transcription factors are predominantly affected by the observed DNA methylation?*

When DNA methylation occurs in promoters, it can interfere with transcription factor binding as a mechanism for repressing gene expression. Understanding which transcription factors are primarily affected and if their binding sites are altered across all genes or a subset of genes would provide insight to which upstream regulatory pathways are repressed or potentiated and how that affects downstream gene transcription. This could be achieved by identifying the DNA sequence surrounding or proximal to differentially methylated positions and cross-referencing to transcription factor binding motif databases such as JASPAR or ENCODE.

3. *How do changes in PFC DNA methylation relate to observed pain-related behaviours?*

In humans and animal subjects, chronic pain is associated with a number of supraspinally-mediated comorbidities including anxiety, depression, and cognitive decline. Previous research has successfully correlated DNA methylation changes to measures of pain sensitivity [200], however no one has yet investigated their correlation to affective-cognitive processes in the context of chronic pain. Correlating DNA methylation to affective-cognitive dimensions of chronic pain would provide insights to underlying mechanisms, and if compared to DNA methylation correlations with pain sensitivity, may allow us to separate sensory from affective-cognitive mechanisms.

4. *What are the cell-type specific DNA methylation changes?*

Each cell type has its own profile of DNA methylation in accordance with its developmental pathway and current cellular activity. Neurons, microglia, and astrocytes all have well-established and separate contributions to the development and maintenance of chronic pain. Performing fluorescence-activated cell sorting (FACS) before analyzing DNA methylation would allow for cell-type specific methylation profiles to be developed and provide greater insight to cell type response to chronic pain.

5. *Do other pain conditions present with overlapping changes in DNA methylation in PFC?*

Previous studies have demonstrated that different chronic pain syndromes have region-specific patterns of brain activation [460]. As a central integrator of ascending nociceptive input, cognitive and affective responses to pain, and descending modulation, the PFC response to different pain models may vary as well. Utilizing different animal models such as chronic constriction injury, which produces a chronic resolving neuropathy, or induction of chronic inflammatory pain through the destruction of tissues surrounding a joint, may reveal different PFC methylation responses. Understanding commonalities and differences across types of pain will provide insights into the generalizability of these findings and to the potential therapeutic implications.

6.4. Contribution to the Scientific Literature

By examining the relationship between chronic pain and PFC DNA methylation, the work in this thesis consists of several novel contributions to the field of pain research. The significance and impact of these contributions have been discussed in context of the

existing knowledge in the manuscripts and discussion above. They are concisely summarized here:

1. PFC DNA methylation undergoes dynamic and robust changes across the time course of chronic neuropathic pain onset, development, and maintenance, suggesting a time-dependent regulation of gene expression. This study was also the first to show rapid changes in PFC DNA methylation one day after injury.

Topham, L., Gregoire, S., Kang, H., Salmon-Divon, M., Lax, E., Millecamps, M., Szyf, M., & Stone, L. S. (2020). The transition from acute to chronic pain: dynamic epigenetic reprogramming of the mouse prefrontal cortex up to 1 year after nerve injury. *Pain*, *161*(10), 2394–2409.

2. Chronic SAM treatment associated with successful pain attenuation induces changes in PFC DNA methylation at thousands of gene promoters.

Topham, L., Gregoire, S., Kang, H., Salmon-Divon, M., Lax, E., Millecamps, M., Szyf, M., & Stone, L. S. Attenuation of neuropathic pain by SAM is associated with genome-wide reversals of nerve injury induced changes in DNA methylation. *In preparation*

3. Long-term running exercise associated with successful pain attenuation induces changes in PFC DNA methylation at thousands of gene promoters.

Topham, L., Gregoire, S., Kang, H., Salmon-Divon, M., Lax, E., Millecamps, M., Szyf, M., & Stone, L. S. Attenuation of neuropathic pain through voluntary exercise is associated with genome-wide reversals of nerve injury induced changes in DNA methylation. *In preparation*

4. Successful attenuation of neuropathic pain by either SAM treatment or exercise causes a reversal in DNA methylation, correcting pain-induced DNA methylation changes. While this is consistent with work from other domains, we were the first to demonstrate it in a model of chronic pain.

Topham, L., Gregoire, S., Kang, H., Salmon-Divon, M., Lax, E., Millecamps, M., Szyf, M., & Stone, L. S. Attenuation of neuropathic pain by SAM is associated with genome-wide reversals of nerve injury induced changes in DNA methylation. *In preparation*

Topham, L., Gregoire, S., Kang, H., Salmon-Divon, M., Lax, E., Millecamps, M., Szyf, M., & Stone, L. S. Attenuation of neuropathic pain through voluntary exercise is associated with genome-wide reversals of nerve injury induced changes in DNA methylation. *In preparation*

To Whom it May Concern:

This letter confirms that permission to use Figure 1 from the article "Epigenetics and human disease: translating basic biology into clinical applications", CMAJ January 31, 2006 174 (3) 341-348; DOI: https://doi.org/10.1503/cmaj.050774 has been granted for the following:

Name: Lucas Topham
Organization: McGill University
Use: Thesis/Dissertation
Title: Chronic Pain and DNA Methylation in the Mouse Prefrontal Cortex
Format: Both print and electronic
Release Date: December 2020
